MC9S12P128
Reference Manual

Covers also MC9S12P-Family
MC9S12P96
MC9S12P64
MC9S12P32

MC9S12P128RMV1
Rev. 1.13
23 April 2010
freescale.com
To provide the most up-to-date information, the revision of our documents on the World Wide Web will be the most current. Your printed copy may be an earlier revision. To verify you have the latest information available, refer to:

http://freescale.com/

A full list of family members and options is included in the appendices.

The following revision history table summarizes changes contained in this document.

This document contains information for all constituent modules, with the exception of the CPU. For CPU information please refer to CPU12-1 in the CPU12 & CPU12X Reference Manual.

### Revision History

Chapter 1 Device Overview MC9S12P-Family

1.1 Introduction ................................................................. 17
1.2 Features .......................................................................... 17
  1.2.1 MC9S12P Family Comparison ..................................... 18
  1.2.2 Chip-Level Features .................................................. 18
1.3 Module Features .............................................................. 19
  1.3.1 S12 16-Bit Central Processor Unit (CPU) ...................... 19
  1.3.2 On-Chip Flash with ECC ............................................. 19
  1.3.3 On-Chip SRAM .......................................................... 20
  1.3.4 Main External Oscillator (XOSC) .............................. 20
  1.3.5 Internal RC Oscillator (IRC) ...................................... 20
  1.3.6 Internal Phase-Locked Loop (IPLL) ......................... 20
  1.3.7 System Integrity Support .......................................... 20
  1.3.8 Timer (TIM) ............................................................ 21
  1.3.9 Pulse Width Modulation Module (PWM) ................. 21
  1.3.10 Controller Area Network Module (MSCAN) .......... 21
  1.3.11 Serial Communication Interface Module (SCI) .......... 21
  1.3.12 Serial Peripheral Interface Module (SPI) ............... 22
  1.3.13 Analog-to-Digital Converter Module (ATD) ............ 22
  1.3.14 On-Chip Voltage Regulator (VREG) ....................... 22
  1.3.15 Background Debug (BDM) ...................................... 22
  1.3.16 Debugger (DBG) .................................................... 23
1.4 Block Diagram ............................................................... 24
1.5 Device Memory Map ....................................................... 25
1.6 Part ID Assignments ......................................................... 28
1.7 Signal Description .......................................................... 28
  1.7.1 Device Pinout ......................................................... 29
  1.7.2 Pin Assignment Overview ....................................... 31
  1.7.3 Detailed Signal Descriptions .................................. 38
  1.7.4 Power Supply Pins ................................................. 41
1.8 System Clock Description ................................................. 42
1.9 Modes of Operation ....................................................... 42
  1.9.1 Chip Configuration Summary .................................. 43
  1.9.2 Low Power Operation ............................................. 44
1.10 Security ......................................................................... 44
1.11 Resets and Interrupts ...................................................... 44
  1.11.1 Resets ................................................................. 44
  1.11.2 Interrupt Vectors ................................................ 44
  1.11.3 Effects of Reset ................................................... 46
1.12 COP Configuration ......................................................... 47
1.13 ATD External Trigger Input Connection ............................ 47

Freescale Semiconductor
Chapter 2
Port Integration Module (S12PPIMV1)

2.1 Introduction ......................................................... 49
  2.1.1 Overview ..................................................... 49
  2.1.2 Features ...................................................... 50

2.2 External Signal Description ..................................... 50

2.3 Memory Map and Register Definition ............................ 52
  2.3.1 Memory Map .................................................. 52
  2.3.2 Register Descriptions ....................................... 61
  2.3.3 Port A Data Register (PORTA) ................................ 63
  2.3.4 Port B Data Register (PORTB) ................................ 63
  2.3.5 Port A Data Direction Register (DDRA) ....................... 64
  2.3.6 Port B Data Direction Register (DDRB) ....................... 64
  2.3.7 PIM Reserved Register ....................................... 65
  2.3.8 Port E Data Register (PORTE) ................................ 65
  2.3.9 Port E Data Direction Register (DDRE) ....................... 66
  2.3.10 Ports A, B, E, BKGD pin Pull-up Control Register (PUCR) 67
  2.3.11 Ports A, B, E Reduced Drive Register (RDRIV) ............. 68
  2.3.12 ECLK Control Register (ECLKCTL) .......................... 69
  2.3.13 PIM Reserved Register ....................................... 69
  2.3.14 IRQ Control Register (IRQCR) ............................... 70
  2.3.15 PIM Reserved Register ....................................... 70
  2.3.16 Port T Data Register (PTT) .................................. 71
  2.3.17 Port T Input Register (PTIT) ................................ 72
  2.3.18 Port T Data Direction Register (DDRT) ....................... 73
  2.3.19 Port T Reduced Drive Register (RDRT) ....................... 74
  2.3.20 Port T Pull Device Enable Register (PERT) .................. 74
  2.3.21 Port T Polarity Select Register (PPST) ....................... 75
  2.3.22 PIM Reserved Register ....................................... 75
  2.3.23 Port T Routing Register (PTTRR) ............................ 76
  2.3.24 Port S Data Register (PTS) .................................. 77
  2.3.25 Port S Input Register (PTIS) ................................ 77
  2.3.26 Port S Data Direction Register (DDRS) ....................... 78
  2.3.27 Port S Reduced Drive Register (RDRS) ....................... 79
  2.3.28 Port S Pull Device Enable Register (PERS) .................. 79
  2.3.29 Port S Polarity Select Register (PPSS) ....................... 80
  2.3.30 Port S Wired-Or Mode Register (WOMS) ...................... 80
  2.3.31 PIM Reserved Register ....................................... 81
  2.3.32 Port M Data Register (PTM) .................................. 81
  2.3.33 Port M Input Register (PTIM) ................................ 82
  2.3.34 Port M Data Direction Register (DDRM) ....................... 83
  2.3.35 Port M Reduced Drive Register (RDRM) ....................... 84
  2.3.36 Port M Pull Device Enable Register (PERM) .................. 85
2.3.37 Port M Polarity Select Register (PPSM) ....................................................... 85
2.3.38 Port M Wired-Or Mode Register (WOMM) ................................................. 86
2.3.39 PIM Reserved Register ................................................................. 86
2.3.40 Port P Data Register (PTP) .............................................................. 87
2.3.41 Port P Input Register (PTIP) ............................................................. 88
2.3.42 Port P Data Direction Register (DDRP) .............................................. 88
2.3.43 Port P Reduced Drive Register (RDRP) ............................................... 89
2.3.44 Port P Pull Device Enable Register (PERP) ....................................... 90
2.3.45 Port P Polarity Select Register (PPSP) ............................................. 90
2.3.46 Port P Interrupt Enable Register (PIEP) ......................................... 91
2.3.47 Port P Interrupt Flag Register (PIFP) ............................................. 91
2.3.48 PIM Reserved Registers ............................................................ 92
2.3.49 Port J Data Register (PTJ) .............................................................. 92
2.3.50 Port J Input Register (PTIJ) ............................................................. 93
2.3.51 Port J Data Direction Register (DDRJ) .............................................. 93
2.3.52 Port J Reduced Drive Register (RDRJ) ............................................. 94
2.3.53 Port J Pull Device Enable Register (PERJ) ..................................... 94
2.3.54 Port J Polarity Select Register (PPSJ) ............................................. 95
2.3.55 Port J Interrupt Enable Register (PIEJ) ......................................... 95
2.3.56 Port J Interrupt Flag Register (PIFJ) ............................................. 96
2.3.57 Port AD Data Register (PT0AD) ....................................................... 96
2.3.58 Port AD Data Register (PT1AD) ....................................................... 97
2.3.59 Port AD Data Direction Register (DDR0AD) ..................................... 97
2.3.60 Port AD Data Direction Register (DDR1AD) .................................... 98
2.3.61 Port AD Reduced Drive Register (RDR0AD) .................................... 98
2.3.62 Port AD Reduced Drive Register (RDR1AD) .................................... 99
2.3.63 Port AD Pull Up Enable Register (PER0AD) .................................. 99
2.3.64 Port AD Pull Up Enable Register (PER1AD) .................................. 100
2.3.65 PIM Reserved Registers ............................................................ 100

2.4 Functional Description ................................................................. 100
  2.4.1 General ................................................................. 100
  2.4.2 Registers ................................................................. 100
  2.4.3 Pins and Ports .......................................................... 103
  2.4.4 Pin interrupts .......................................................... 105

2.5 Initialization Information .......................................................... 106
  2.5.1 Port Data and Data Direction Register writes .................................. 106

Chapter 3
Memory Map Control (S12PMMCV1)

3.1 Introduction ................................................................. 107
  3.1.1 Glossary ................................................................. 107
  3.1.2 Overview ................................................................. 108
  3.1.3 Features ................................................................. 108
  3.1.4 Modes of Operation .................................................. 108
  3.1.5 Block Diagram ......................................................... 108

S12P-Family Reference Manual, Rev. 1.13
Chapter 4
Interrupt Module (S12SINTV1)

4.1 Introduction .................................................................................................................. 123
  4.1.1 Glossary .................................................................................................................. 123
  4.1.2 Features ................................................................................................................... 123
  4.1.3 Modes of Operation ............................................................................................... 124
  4.1.4 Block Diagram ....................................................................................................... 124

4.2 External Signal Description ......................................................................................... 125

4.3 Memory Map and Register Definition ......................................................................... 125
  4.3.1 Register Descriptions ............................................................................................. 125

4.4 Functional Description ................................................................................................. 126
  4.4.1 S12S Exception Requests ....................................................................................... 126
  4.4.2 Interrupt Prioritization .......................................................................................... 126
  4.4.3 Reset Exception Requests ...................................................................................... 127
  4.4.4 Exception Priority ................................................................................................. 127

4.5 Initialization/Application Information .......................................................................... 128
  4.5.1 Initialization ............................................................................................................ 128
  4.5.2 Interrupt Nesting .................................................................................................... 128
  4.5.3 Wake Up from Stop or Wait Mode ......................................................................... 128

Chapter 5
Background Debug Module (S12SBDMV1)

5.1 Introduction .................................................................................................................... 131
  5.1.1 Features .................................................................................................................. 132
  5.1.2 Modes of Operation ............................................................................................... 132
  5.1.3 Block Diagram ....................................................................................................... 133

5.2 External Signal Description ......................................................................................... 133

5.3 Memory Map and Register Definition ......................................................................... 134
  5.3.1 Module Memory Map ............................................................................................. 134
  5.3.2 Register Descriptions ............................................................................................. 134
  5.3.3 Family ID Assignment ............................................................................................ 138
Chapter 6
S12S Debug Module (S12SDBGV2)

6.1 Introduction ................................................................. 155
  6.1.1 Glossary Of Terms .................................................. 155
  6.1.2 Overview ............................................................... 156
  6.1.3 Features ............................................................... 156
  6.1.4 Modes of Operation ................................................ 157
  6.1.5 Block Diagram ...................................................... 157

6.2 External Signal Description ........................................... 157

6.3 Memory Map and Registers ............................................ 158
  6.3.1 Module Memory Map ................................................ 158
  6.3.2 Register Descriptions ............................................. 159

6.4 Functional Description ................................................. 174
  6.4.1 S12SDBG Operation ................................................ 174
  6.4.2 Comparator Modes ................................................ 175
  6.4.3 Match Modes (Forced or Tagged) ................................ 179
  6.4.4 State Sequence Control ......................................... 180
  6.4.5 Trace Buffer Operation ......................................... 181
  6.4.6 Tagging .............................................................. 187
  6.4.7 Breakpoints ........................................................ 187

6.5 Application Information ................................................ 189
  6.5.1 State Machine scenarios ........................................... 189
  6.5.2 Scenario 1 ............................................................ 190
  6.5.3 Scenario 2 ............................................................ 190
  6.5.4 Scenario 3 ............................................................ 191
  6.5.5 Scenario 4 ............................................................ 191
  6.5.6 Scenario 5 ............................................................ 192
  6.5.7 Scenario 6 ............................................................ 192
  6.5.8 Scenario 7 ............................................................ 192
  6.5.9 Scenario 8 ............................................................ 193
  6.5.10 Scenario 9 ........................................................... 194
  6.5.11 Scenario 10 .......................................................... 194

S12P-Family Reference Manual, Rev. 1.13
Chapter 7
S12 Clock, Reset and Power Management Unit (S12CPMU)

7.1 Introduction ................................................................. 197
  7.1.1 Features ............................................................... 197
  7.1.2 Modes of Operation ................................................ 199
  7.1.3 S12CPMU Block Diagram ........................................... 201
7.2 Signal Description ....................................................... 202
  7.2.1 RESET ................................................................. 202
  7.2.2 EXTL and XTAL ..................................................... 202
  7.2.3 TEMPERATURE — temperature sensor output voltage ........... 203
  7.2.4 VDDR — Regulator Power Input Pin ............................. 203
  7.2.5 VDDA, VSSA — Regulator Reference Supply Pins ............... 203
  7.2.6 VSS, VSSPLL— Ground Pins .................................... 203
  7.2.7 VDDX, VSSX— Pad Supply Pins ................................ 203
  7.2.8 API_EXTCLK — API external clock output pin .................. 203
7.3 Memory Map and Registers ............................................ 204
  7.3.1 Module Memory Map ............................................... 204
  7.3.2 Register Descriptions ........................................... 206
7.4 Functional Description ................................................. 237
  7.4.1 Phase Locked Loop with Internal Filter (PLL) ................. 237
  7.4.2 Startup from Reset ............................................... 239
  7.4.3 Stop Mode using PLLCLK as Bus Clock ......................... 239
  7.4.4 Full Stop Mode using Oscillator Clock as Bus Clock .......... 240
  7.4.5 External Oscillator ............................................. 241
  7.4.6 System Clock Configurations ................................... 244
7.5 Resets ................................................................. 246
  7.5.1 General ............................................................ 246
  7.5.2 Description of Reset Operation ................................ 246
  7.5.3 Power-On Reset (POR) ........................................... 248
  7.5.4 Low-Voltage Reset (LVR) ....................................... 248
7.6 Interrupts ............................................................. 248
  7.6.1 Description of Interrupt Operation ............................. 249
7.7 Initialization/Application Information ................................ 250

Chapter 8
Freescale’s Scalable Controller Area Network (S12MSCANV3)

8.1 Introduction ............................................................. 251
  8.1.1 Glossary ............................................................ 252
  8.1.2 Block Diagram ..................................................... 252
  8.1.3 Features ............................................................ 253
  8.1.4 Modes of Operation ............................................. 253
8.2 External Signal Description ......................................... 253
  8.2.1 RXCAN — CAN Receiver Input Pin ............................... 253
  8.2.2 TXCAN — CAN Transmitter Output Pin ......................... 254
Chapter 9
Analog-to-Digital Converter (ADC12B10C)

9.1 Introduction ........................................................................................................ 305
  9.1.1 Features ........................................................................................................ 305
  9.1.2 Modes of Operation ....................................................................................... 306
  9.1.3 Block Diagram ............................................................................................... 307
9.2 Signal Description ................................................................................................ 308
  9.2.1 Detailed Signal Descriptions ........................................................................ 308
9.3 Memory Map and Register Definition ................................................................ 308
  9.3.1 Module Memory Map ..................................................................................... 308
  9.3.2 Register Descriptions ..................................................................................... 310
9.4 Functional Description ........................................................................................ 324
  9.4.1 Analog Sub-Block .......................................................................................... 325
  9.4.2 Digital Sub-Block ............................................................................................ 325
9.5 Resets .................................................................................................................. 326
9.6 Interrupts .............................................................................................................. 327

Chapter 10
Pulse-Width Modulator (PWM8B6CV1) Block Description

10.1 Introduction ............................................................................................................ 329
  10.1.1 Features ....................................................................................................... 329
  10.1.2 Modes of Operation ...................................................................................... 329
  10.1.3 Block Diagram .............................................................................................. 330
10.2 External Signal Description ................................................................................. 330
  10.2.1 PWM5 — Pulse Width Modulator Channel 5 Pin ......................................... 330
  10.2.2 PWM4 — Pulse Width Modulator Channel 4 Pin ......................................... 330
  10.2.3 PWM3 — Pulse Width Modulator Channel 3 Pin ......................................... 330
Chapter 11
Serial Communication Interface (S12SCIV5)

11.1 Introduction ......................................................... 363
  11.1.1 Glossary ....................................................... 363
  11.1.2 Features ......................................................... 364
  11.1.3 Modes of Operation ............................................ 364
  11.1.4 Block Diagram .................................................. 365
11.2 External Signal Description ........................................ 365
  11.2.1 TXD — Transmit Pin ......................................... 365
  11.2.2 RXD — Receive Pin ............................................ 365
11.3 Memory Map and Register Definition ............................... 365
  11.3.1 Module Memory Map and Register Definition .................. 366
  11.3.2 Register Descriptions ......................................... 366
11.4 Functional Description ............................................. 376
  11.4.1 Infrared Interface Submodule .................................. 377
  11.4.2 LIN Support ..................................................... 378
  11.4.3 Data Format ..................................................... 378
  11.4.4 Baud Rate Generation ........................................... 380
  11.4.5 Transmitter ..................................................... 381
  11.4.6 Receiver ......................................................... 386
  11.4.7 Single-Wire Operation ......................................... 394
  11.4.8 Loop Operation ................................................ 395
11.5 Initialization/Application Information ............................ 395
  11.5.1 Reset Initialization ............................................. 395
  11.5.2 Modes of Operation ............................................ 395
  11.5.3 Interrupt Operation ............................................ 396
  11.5.4 Recovery from Wait Mode ...................................... 398
  11.5.5 Recovery from Stop Mode ...................................... 398

Chapter 12
Serial Peripheral Interface (S12SPIV5)

12.1 Introduction ......................................................... 399
Chapter 13
128 KByte Flash Module (S12FTMRC128K1V1)

13.1 Introduction ................................................................. 425
  13.1.1 Glossary .............................................................. 426
  13.1.2 Features .............................................................. 427
  13.1.3 Block Diagram ...................................................... 427
13.2 External Signal Description ............................................... 428
  13.2.1 MOSI — Master Out/Slave In Pin .............................. 428
  13.2.2 MISO — Master In/Slave Out Pin .............................. 428
  13.2.3 SS — Slave Select Pin ............................................. 428
  13.2.4 SCK — Serial Clock Pin ........................................... 429
13.3 Memory Map and Registers ............................................... 429
  13.3.1 Module Memory Map ............................................... 429
  13.3.2 Register Descriptions ............................................ 432
13.4 Functional Description .................................................. 440
  13.4.1 Master Mode ....................................................... 440
  13.4.2 Slave Mode ........................................................ 440
  13.4.3 Transmission Formats ............................................. 440
  13.4.4 SPI Baud Rate Generation ....................................... 440
  13.4.5 Special Features .................................................. 440
  13.4.6 Error Conditions .................................................. 440
  13.4.7 Low Power Mode Options ....................................... 440
  13.4.8 Stop Mode ........................................................ 440
  13.4.9 Wait Mode ........................................................ 440
  13.4.10 Flash Command Description .................................... 440
  13.4.11 Allowed Simultaneous P-Flash and D-Flash Operations .... 440
  13.4.12 Interrupts .......................................................... 440
  13.4.13 Wait Mode ........................................................ 440
  13.4.14 Alarms ............................................................. 440
  13.4.15 System Clocks ..................................................... 440
13.5 Security ................................................................. 440
  13.5.1 Unsecuring the MCU using Backdoor Key Access .............. 440
  13.5.2 Unsecuring the MCU in Special Single Chip Mode using BDM . 440
  13.5.3 Mode and Security Effects on Flash Command Availability ... 440
13.6 Initialization .............................................................. 440

S12P-Family Reference Manual, Rev. 1.13
Chapter 14
Timer Module (TIM16B8CV2) Block Description

14.1 Introduction .................................................................................................................. 473

Chapter 1 Device Overview MC9S12P-Family

1.1 Introduction

The MC9S12P family is an optimized, automotive, 16-bit microcontroller product line focused on low-cost, high-performance, and low pin-count. This family is intended to bridge between high-end 8-bit microcontrollers and high-performance 16-bit microcontrollers, such as the MC9S12XS family. The MC9S12P family is targeted at generic automotive applications requiring CAN or LIN/J2602 communication. Typical examples of these applications include body controllers, occupant detection, door modules, seat controllers, RKE receivers, smart actuators, lighting modules, and smart junction boxes.

The MC9S12P family uses many of the same features found on the MC9S12XS family, including error correction code (ECC) on flash memory, a separate data-flash module for diagnostic or data storage, a fast analog-to-digital converter (ATD) and a frequency modulated phase locked loop (IPLL) that improves the EMC performance.

The MC9S12P family deliver all the advantages and efficiencies of a 16-bit MCU while retaining the low cost, power consumption, EMC, and code-size efficiency advantages currently enjoyed by users of Freescale’s existing 8-bit and 16-bit MCU families. Like the MC9S12XS family, the MC9S12P family run 16-bit wide accesses without wait states for all peripherals and memories. The MC9S12P family is available in 80-pin QFP, 64-pin LQFP, and 48-pin QFN package options and aims to maximize pin compatibility with the MC9S12XS family. In addition to the I/O ports available in each module, further I/O ports are available with interrupt capability allowing wake-up from stop or wait modes.

1.2 Features

This section describes the key features of the MC9S12P family.
1.2.1 MC9S12P Family Comparison

Table 1 provides a summary of different members of the MC9S12P family and their proposed features. This information is intended to provide an understanding of the range of functionality offered by this microcontroller family.

1. P or D Flash erasing or programming requires a minimum bus frequency of 1MHz

1.2.2 Chip-Level Features

On-chip modules available within the family include the following features:

- S12 CPU core
- Up to 128 Kbyte on-chip flash with ECC
- 4 Kbyte data flash with ECC
- Up to 6 Kbyte on-chip SRAM
- Phase locked loop (IPLL) frequency multiplier with internal filter
- 4–16 MHz amplitude controlled Pierce oscillator
- 1 MHz internal RC oscillator
- Timer module (TIM) supporting input/output channels that provide a range of 16-bit input capture, output compare, counter, and pulse accumulator functions
- Pulse width modulation (PWM) module with 6 x 8-bit channels
- 10-channel, 12-bit resolution successive approximation analog-to-digital converter (ATD)
- One serial peripheral interface (SPI) module
- One serial communication interface (SCI) module supporting LIN communications
- One multi-scalable controller area network (MSCAN) module (supporting CAN protocol 2.0A/B)
- On-chip voltage regulator (VREG) for regulation of input supply and all internal voltages
- Autonomous periodic interrupt (API)

1.3 Module Features

The following sections provide more details of the modules implemented on the MC9S12P family.

1.3.1 S12 16-Bit Central Processor Unit (CPU)

S12 CPU is a high-speed 16-bit processing unit:
- Full 16-bit data paths supports efficient arithmetic operation and high-speed math execution
- Includes many single-byte instructions. This allows much more efficient use of ROM space.
- Extensive set of indexed addressing capabilities, including:
  — Using the stack pointer as an indexing register in all indexed operations
  — Using the program counter as an indexing register in all but auto increment/decrement mode
  — Accumulator offsets using A, B, or D accumulators
  — Automatic index predecrement, preincrement, postdecrement, and postincrement (by –8 to +8)

1.3.2 On-Chip Flash with ECC

On-chip flash memory on the MC9S12P features the following:
- Up to 128 Kbyte of program flash memory
  — 32 data bits plus 7 syndrome ECC (error correction code) bits allow single bit error correction and double fault detection
  — Erase sector size 512 bytes
  — Automated program and erase algorithm
  — User margin level setting for reads
  — Protection scheme to prevent accidental program or erase
- 4 Kbyte data flash space
  — 16 data bits plus 6 syndrome ECC (error correction code) bits allow single bit error correction and double fault detection
  — Erase sector size 256 bytes
  — Automated program and erase algorithm
  — User margin level setting for reads
1.3.3 **On-Chip SRAM**

- Up to 6 Kbytes of general-purpose RAM

1.3.4 **Main External Oscillator (XOSC)**

- Loop control Pierce oscillator using a 4 MHz to 16 MHz crystal
  - Current gain control on amplitude output
  - Signal with low harmonic distortion
  - Low power
  - Good noise immunity
  - Eliminates need for external current limiting resistor
  - Transconductance sized for optimum start-up margin for typical crystals

1.3.5 **Internal RC Oscillator (IRC)**

- Trimmable internal reference clock.
  - Frequency: 1 MHz
  - Trimmed accuracy over –40°C to +125°C ambient temperature range: ±1.5%

1.3.6 **Internal Phase-Locked Loop (IPLL)**

- Phase-locked-loop clock frequency multiplier
  - No external components required
  - Reference divider and multiplier allow large variety of clock rates
  - Automatic bandwidth control mode for low-jitter operation
  - Automatic frequency lock detector
  - Configurable option to spread spectrum for reduced EMC radiation (frequency modulation)
  - Reference clock sources:
    - External 4–16 MHz resonator/crystal (XOSC)
    - Internal 1 MHz RC oscillator (IRC)

1.3.7 **System Integrity Support**

- Power-on reset (POR)
- System reset generation
- Illegal address detection with reset
- Low-voltage detection with interrupt or reset
- Real time interrupt (RTI)
- Computer operating properly (COP) watchdog
  - Configurable as window COP for enhanced failure detection
1.3.8 **Timer (TIM)**
- 8 x 16-bit channels for input capture or output compare
- 16-bit free-running counter with 7-bit precision prescaler
- 1 x 16-bit pulse accumulator

1.3.9 **Pulse Width Modulation Module (PWM)**
- 6 channel x 8-bit or 3 channel x 16-bit pulse width modulator
  - Programmable period and duty cycle per channel
  - Center-aligned or left-aligned outputs
  - Programmable clock select logic with a wide range of frequencies

1.3.10 **Controller Area Network Module (MSCAN)**
- 1 Mbit per second, CAN 2.0 A, B software compatible
  - Standard and extended data frames
  - 0–8 bytes data length
  - Programmable bit rate up to 1 Mbps
- Five receive buffers with FIFO storage scheme
- Three transmit buffers with internal prioritization
- Flexible identifier acceptance filter programmable as:
  - 2 x 32-bit
  - 4 x 16-bit
  - 8 x 8-bit
- Wakeup with integrated low pass filter option
- Loop back for self test
- Listen-only mode to monitor CAN bus
- Bus-off recovery by software intervention or automatically
- 16-bit time stamp of transmitted/received messages

1.3.11 **Serial Communication Interface Module (SCI)**
- Full-duplex or single-wire operation
- Standard mark/space non-return-to-zero (NRZ) format
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse widths
- 13-bit baud rate selection
• Programmable character length
• Programmable polarity for transmitter and receiver
• Active edge receive wakeup
• Break detect and transmit collision detect supporting LIN

1.3.12 Serial Peripheral Interface Module (SPI)
• Configurable 8- or 16-bit data size
• Full-duplex or single-wire bidirectional
• Double-buffered transmit and receive
• Master or slave mode
• MSB-first or LSB-first shifting
• Serial clock phase and polarity options

1.3.13 Analog-to-Digital Converter Module (ATD)
• 10-channel, 12-bit analog-to-digital converter
  — 3 us single conversion time
  — 8-/10-/12-bit resolution
  — Left or right justified result data
  — Internal oscillator for conversion in stop modes
  — Wakeup from low power modes on analog comparison > or <= match
  — Continuous conversion mode
  — Multiple channel scans
• Pins can also be used as digital I/O

1.3.14 On-Chip Voltage Regulator (VREG)
• Linear voltage regulator with bandgap reference
• Low-voltage detect (LVD) with low-voltage interrupt (LVI)
• Power-on reset (POR) circuit
• Low-voltage reset (LVR)
• High temperature sensor

1.3.15 Background Debug (BDM)
• Non-intrusive memory access commands
• Supports in-circuit programming of on-chip nonvolatile memory
1.3.16 Debugger (DBG)

- Trace buffer with depth of 64 entries
- Three comparators (A, B and C)
  - Comparators A compares the full address bus and full 16-bit data bus
  - Exact address or address range comparisons
- Two types of comparator matches
  - Tagged  This matches just before a specific instruction begins execution
  - Force  This is valid on the first instruction boundary after a match occurs
- Four trace modes
- Four stage state sequencer

NOTE

Reserved register space shown in Table 1-2 is not allocated to any module. This register space is reserved for future use. Writing to these locations have no effect. Read access to these locations returns zero.

Figure 1-2 shows S12P CPU and BDM local address translation to the global memory map. It indicates also the location of the internal resources in the memory map. Table 1-3. shows the mapping of D-Flash and unpaged P-Flash memory. The whole 256K global memory space is visible through the P-Flash window located in the 64k local memory map located at 0x8000 - 0xBFFF using the PPAGE register.

1.6 Part ID Assignments

The part ID is located in two 8-bit registers PARTIDH and PARTIDL (addresses 0x001A and 0x001B). The read-only value is a unique part ID for each revision of the chip. Table 1-5 shows the assigned part ID number and Mask Set number.

The Version ID in Table 1-5, is a word located in a flash information row. The version ID number indicates a specific version of internal NVM controller.

1. Table shows a superset of pin functions. Not all functions are available on all derivatives.
2. VRH and VDDA share single pin on 48 pin package option.
3. VRL and VSSA share single pin on 64 and 48 pin package option.
1.7.3  Detailed Signal Descriptions

1.7.3.1  EXTAL, XTAL — Oscillator Pins
EXTAL and XTAL are the crystal driver and external clock pins. On reset all the device clocks are derived from the internal reference clock. XTAL is the oscillator output.

1.7.3.2  RESET — External Reset Pin
The RESET pin is an active low bidirectional control signal. It acts as an input to initialize the MCU to a known start-up state, and an output when an internal MCU function causes a reset. The RESET pin has an internal pull-up device.

1.7.3.3  TEST — Test Pin
This input only pin is reserved for factory test. This pin has an internal pull-down device.

    NOTE

    The TEST pin must be tied to VSSX in all applications.

1.7.3.4  BKGD / MODC — Background Debug and Mode Pin
The BKGD/MODC pin is used as a pseudo-open-drain pin for the background debug communication. It is used as a MCU operating mode select pin during reset. The state of this pin is latched to the MODC bit at the rising edge of RESET. The BKGD pin has an internal pull-up device.

1.7.3.5  PAD[9:0] / AN[9:0] — Port AD Input Pins of ATD
PAD[9:0] are general-purpose input or output pins and analog inputs AN[9:0] of the analog-to-digital converter ATD.

1.7.3.6  PA[7:0] — Port A I/O Pins
PA[7:0] are general-purpose input or output pins.

1.7.3.7  PB[7:0] — Port B I/O Pins
PB[7:0] are general-purpose input or output pins.

1.7.3.8  PE7 — Port E I/O Pin 7 / ECLKX2
PE7 is a general-purpose input or output pin. An internal pull-up is enabled during reset. It can be configured to output ECLKX2.

1.7.3.9  PE[6:5] — Port E I/O Pin 6-5
PE[6:5] are a general-purpose input or output pins.
1.7.3.10  **PE4 / ECLK — Port E I/O Pin 4**

PE4 is a general-purpose input or output pin. It can be configured to drive the internal bus clock ECLK. ECLK can be used as a timing reference. The ECLK output has a programmable prescaler.

1.7.3.11  **PE[3:2] — Port E I/O Pin 3**

PE[3:2] are a general-purpose input or output pins.

1.7.3.12  **PE1 / IRQ — Port E Input Pin 1**

PE1 is a general-purpose input pin and the maskable interrupt request input that provides a means of applying asynchronous interrupt requests. This will wake up the MCU from stop or wait mode.

1.7.3.13  **PE0 / XIRQ — Port E Input Pin 0**

PE0 is a general-purpose input pin and the non-maskable interrupt request input that provides a means of applying asynchronous interrupt requests. This will wake up the MCU from stop or wait mode. The XIRQ interrupt is level sensitive and active low. As XIRQ is level sensitive, while this pin is low the MCU will not enter STOP mode.

1.7.3.14  **PJ[7:6, 2:0] / KWJ[7:6, 2:0] — Port J I/O Pins 7-6, 2-0**

PJ[7:6, 2:0] are a general-purpose input or output pins. They can be configured as keypad wakeup inputs.

1.7.3.15  **PM[7:6] — Port M I/O Pins 7-6**

PM[7:6] are a general-purpose input or output pins.

1.7.3.16  **PM5 / SCK — Port M I/O Pin 5**

PM5 is a general-purpose input or output pin. It can be configured as the serial clock pin SCK of the serial peripheral interface (SPI).

1.7.3.17  **PM4 / MOSI — Port M I/O Pin 4**

PM4 is a general-purpose input or output pin. It can be configured as the master output (during master mode) or slave input pin (during slave mode) MOSI for the serial peripheral interface (SPI).

1.7.3.18  **PM3 / SS — Port M I/O Pin 3**

PM3 is a general-purpose input or output pin. It can be configured as the slave select pin SS of the serial peripheral interface (SPI).

1.7.3.19  **PM2 / MISO — Port M I/O Pin 3**

PM2 is a general-purpose input or output pin. It can be configured as the master input (during master mode) or slave output pin (during slave mode) MISO for the serial peripheral interface (SPI)
1.7.3.20 PM1 / TXCAN — Port M I/O Pin 1
PM1 is a general-purpose input or output pin. It can be configured as the transmit pin TXCAN of the scalable controller area network controller (CAN).

1.7.3.21 PM0 / RXCAN — Port M I/O Pin 0
PM0 is a general-purpose input or output pin. It can be configured as the receive pin RXCAN of the scalable controller area network controller (CAN).

PP[5:0] are a general-purpose input or output pins. They can be configured as keypad wakeup inputs. They can be configured as pulse width modulator (PWM) channel 5-0 output.

1.7.3.23 PP7 / KWP7 — Port P I/O Pin 7
PP7 is a general-purpose input or output pin. It can be configured as a keypad wakeup input.

1.7.3.24 PS3 — Port S I/O Pin 3
PS3 is a general-purpose input or output pin.

1.7.3.25 PS2 — Port S I/O Pin 2
PS2 is a general-purpose input or output pin.

1.7.3.26 PS1 / TXD — Port S I/O Pin 1
PS1 is a general-purpose input or output pin. It can be configured as the transmit pin TXD of serial communication interface (SCI).

1.7.3.27 PS0 / RXD — Port S I/O Pin 0
PS0 is a general-purpose input or output pin. It can be configured as the receive pin RXD of serial communication interface (SCI).

PT[7:6] are general-purpose input or output pins. They can be configured as timer (TIM) channel 7-6.

1.7.3.29 PT5 / IOC5 / PWM5 / API_EXTCLK — Port T I/O Pin 5
PT5 is a general-purpose input or output pin. It can be configured as timer (TIM) channel 5, pulse width modulator (PWM) output 5 or as the output of the API_EXTCLK.
1.7.3.30 PT4 / IOC4 / PWM4 — Port T I/O Pin 4
PT4 is a general-purpose input or output pin. It can be configured as timer (TIM) channel 4 or pulse width modulator (PWM) output 4.

PT[3:1] are a general-purpose input or output pins. They can be configured as timer (TIM) channels 3-1.

1.7.3.32 PT0 / IOC0 / PWM0 — Port T I/O Pin 0
PT0 is a general-purpose input or output pin. It can be configured as timer (TIM) channel 0 or pulse width modulator (PWM) output 0.

1.7.4 Power Supply Pins
MC9S12P-Family power and ground pins are described below.
Because fast signal transitions place high, short-duration current demands on the power supply, use bypass capacitors with high-frequency characteristics and place them as close to the MCU as possible.

NOTE
All VSS pins must be connected together in the application.

1.7.4.1 VDDX[2:1], VSSX[2:1] — Power and Ground Pins for I/O Drivers
External power and ground for I/O drivers. Bypass requirements depend on how heavily the MCU pins are loaded. All VDDX pins are connected together internally. All VSSX pins are connected together internally.

1.7.4.2 VDDR — Power Pin for Internal Voltage Regulator
Power supply input to the internal voltage regulator.

1.7.4.3 VSS3 — Core Ground Pin
The voltage supply of nominally 1.8V is derived from the internal voltage regulator. The return current path is through the VSS3 pin. No static external loading of these pins is permitted.

1.7.4.4 VDDA, VSSA — Power Supply Pins for ATD and Voltage Regulator
These are the power supply and ground input pins for the analog-to-digital converter and the voltage regulator.

1.7.4.5 VRH, VRL — ATD Reference Voltage Input Pins
VRH and VRL are the reference voltage input pins for the analog-to-digital converter.
1.7.4.6 VSSPLL — Ground Pin for PLL

This pin provides ground for the oscillator and the phased-locked loop. The voltage supply of nominally 1.8V is derived from the internal voltage regulator.

1.7.4.7 Power and Ground Connection Summary

1.8 System Clock Description

For the system clock description please refer to chapter Chapter 7, “S12 Clock, Reset and Power Management Unit (S12CPMU).

1.9 Modes of Operation

The MCU can operate in different modes. These are described in 1.9.1 Chip Configuration Summary.

The MCU can operate in different power modes to facilitate power saving when full system performance is not required. These are described in 1.9.2 Low Power Operation.

Some modules feature a software programmable option to freeze the module status whilst the background debug module is active to facilitate debugging.
1.9.1 Chip Configuration Summary

The different modes and the security state of the MCU affect the debug features (enabled or disabled).

The operating mode out of reset is determined by the state of the MODC signal during reset (see Table 1-10). The MODC bit in the MODE register shows the current operating mode and provides limited mode switching during operation. The state of the MODC signal is latched into this bit on the rising edge of RESET.

<table>
<thead>
<tr>
<th>Chip Modes</th>
<th>MODC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal single chip</td>
<td>1</td>
</tr>
<tr>
<td>Special single chip</td>
<td>0</td>
</tr>
</tbody>
</table>

1.9.1.1 Normal Single-Chip Mode

This mode is intended for normal device operation. The opcode from the on-chip memory is being executed after reset (requires the reset vector to be programmed correctly). The processor program is executed from internal memory.

1.9.1.2 Special Single-Chip Mode

This mode is used for debugging single-chip operation, boot-strapping, or security related operations. The background debug module BDM is active in this mode. The CPU executes a monitor program located in an on-chip ROM. BDM firmware waits for additional serial commands through the BKGD pin.
1.9.2 Low Power Operation

The MC9S12P has two static low-power modes Pseudo Stop and Stop Mode. For a detailed description refer to S12CPMU section.

1.10 Security

The MCU security mechanism prevents unauthorized access to the Flash memory. Refer to Section 5.4.1 Security and Section 13.5 Security

1.11 Resets and Interrupts

Consult the S12 CPU manual and the S12SINT section for information on exception processing.

1.11.1 Resets

Table 1-11. lists all Reset sources and the vector locations. Resets are explained in detail in the Section Chapter 7 S12 Clock, Reset and Power Management Unit (S12CPMU)

8.4.7 Interrupts
1.11.3 Effects of Reset

When a reset occurs, MCU registers and control bits are initialized. Refer to the respective block sections for register reset states.

On each reset, the Flash module executes a reset sequence to load Flash configuration registers.

1.11.3.1 Flash Configuration Reset Sequence Phase

On each reset, the Flash module will hold CPU activity while loading Flash module registers from the Flash memory. If double faults are detected in the reset phase, Flash module protection and security may be active on leaving reset. This is explained in more detail in the Flash module section 13.6 Initialization.

1.11.3.2 Reset While Flash Command Active

If a reset occurs while any Flash command is in progress, that command will be immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed.

1.11.3.3 I/O Pins

Refer to the PIM section for reset configurations of all peripheral module ports.

1.11.3.4 Memory

The RAM arrays are not initialized out of reset.

1.12 COP Configuration

The COP time-out rate bits CR[2:0] and the WCOP bit in the CPMUCOP register at address 0x003C are loaded from the Flash register FOPT. See Table 1-13 and Table 1-14 for coding. The FOPT register is loaded from the Flash configuration field byte at global address 0x3_FF0E during the reset sequence.

1.13 ATD External Trigger Input Connection

The ATD module includes external trigger inputs ETRIG0 and ETRIG1. The external trigger allows the user to synchronize ATD conversion to external trigger events. Table 1-15 shows the connection of the external trigger inputs.

Table 1-15. ATD External Trigger Sources

</table>

Consult the ATD section for information about the analog-to-digital converter module. References to freeze mode are equivalent to active BDM mode.
1.14 S12CPMU Configuration

The bandgap reference voltage $V_{BG}$ and the output voltage of the temperature sensor $V_{HT}$ can be connected to the ATD channel SPECIAL17 (see Table 9-15.) using the VSEL (Voltage Access Select Bit) in CPMUHTCTL register (see Table 7-13.)

2.1  Introduction

2.1.1  Overview

The S12P Family Port Integration Module establishes the interface between the peripheral modules and the I/O pins for all ports. It controls the electrical pin properties as well as the signal prioritization and multiplexing on shared pins.

This section covers:

- Port A and B used as general purpose I/O
- Port E associated with the IRQ, XIRQ interrupt inputs
- Port T associated with 1 timer module
- Port S associated with 1 SCI module
- Port M associated with 1 MSCAN and 1 SPI module
- Port P connected to the PWM - inputs can be used as an external interrupt source
- Port J used as general purpose I/O - inputs can be used as an external interrupt source
- Port AD associated with one 10-channel ATD module

Most I/O pins can be configured by register bits to select data direction and drive strength, to enable and select pull-up or pull-down devices.

NOTE

This section assumes the availability of all features (80-pin package option). Some functions are not available on lower pin count package options. Refer to the pin-out summary section.
2.1.2 Features

The Port Integration Module includes these distinctive registers:

- Data registers and data direction registers for Ports A, B, E, T, S, M, P, J and AD when used as general purpose I/O
- Control registers to enable/disable pull devices and select pull-ups/pull-downs on Ports T, S, M, P and J on per-pin basis
- Control registers to enable/disable pull-up devices on Port AD on per-pin basis
- Single control register to enable/disable pull-ups on Ports A, B, and E, on per-port basis and on BKGD pin
- Control registers to enable/disable reduced output drive on Ports T, S, M, P, J and AD on per-pin basis
- Single control register to enable/disable reduced output drive on Ports A, B, and E on per-port basis
- Control registers to enable/disable open-drain (wired-or) mode on Ports S and M
- Interrupt flag register for pin interrupts on Ports P and J
- Control register to configure IRQ pin operation
- Routing register to support module port relocation
- Free-running clock outputs

A standard port pin has the following minimum features:

- Input/output selection
- 5V output drive with two selectable drive strengths
- 5V digital and analog input
- Input with selectable pull-up or pull-down device

Optional features supported on dedicated pins:

- Open drain for wired-or connections
- Interrupt inputs with glitch filtering

2.2 External Signal Description

This section lists and describes the signals that do connect off-chip.

Table 2-1 shows all the pins and their functions that are controlled by the Port Integration Module.

NOTE

If there is more than one function associated with a pin, the priority is indicated by the position in the table from top (highest priority) to bottom (lowest priority).

1. Write access not applicable for one or more register bits. Refer to register description.
2. Refer to device memory map to determine related module.
3. Mode dependent.
4. Read always returns logic level on pins.

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor
2.3.2 Register Descriptions

The following table summarizes the effect of the various configuration bits, i.e. data direction (DDR), output level (IO), reduced drive (RDR), pull enable (PE), pull select (PS) on the pin function and pull device activity.

The configuration bit PS is used for two purposes:
1. Configure the sensitive interrupt edge (rising or falling), if interrupt is enabled.
2. Select either a pull-up or pull-down device if PE is active.
Table 2-3. Pin Configuration Summary

</table>

1. Always ‘0’ on Port A, B, E, and AD.
2. Applicable only on Port P and J.

**NOTE**

All register bits in this module are completely synchronous to internal clocks during a register read.

**NOTE**

Figure of port data registers also display the alternative functions if applicable on the related pin as defined in Table 2-1. Names in brackets denote the availability of the function when using a specific routing option.

**NOTE**

Figures of module routing registers also display the module instance or module channel associated with the related routing bit.
2.3.3 Port A Data Register (PORTA)

Address 0x0000
Access: User read/write(1)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7-0 PA</td>
<td>Port A general purpose input/output data—Data Register&lt;br&gt;The associated pin can be used as general purpose I/O. In general purpose output mode the register bit value is driven to the pin.&lt;br&gt;If the associated data direction bit is set to 1, a read returns the value of the port register bit, otherwise the buffered pin input state is read.</td>
</tr>
</tbody>
</table>

Figure 2-1. Port A Data Register (PORTA)

1. Read: Anytime. The data source is depending on the data direction value.<br>Write: Anytime

2.3.4 Port B Data Register (PORTB)

Address 0x0001
Access: User read/write(1)

<table>

Access: User read/write<sup>(1)</sup>

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 NECLK | No ECLK—Disable ECLK output  
This bit controls the availability of a free-running clock on the ECLK pin. This clock has a fixed rate of equivalent to the internal bus clock.  
1 ECLK disabled  
0 ECLK enabled |
| 6 NCLKX2 | No ECLKX2—Disable ECLKX2 output  
This bit controls the availability of a free-running clock on the ECLKX2 pin. This clock has a fixed rate of twice the internal bus clock.  
1 ECLKX2 disabled  
0 ECLKX2 enabled |
| 5 DIV16 | Free-running ECLK pre-divider—Divide by 16  
This bit enables a divide-by-16 stage on the selected EDIV rate.  
1 Divider enabled: ECLK rate = EDIV rate divided by 16  
0 Divider disabled: ECLK rate = EDIV rate |
| 4-0 EDIV | Free-running ECLK Divider—Configure ECLK rate  
These bits determine the rate of the free-running clock on the ECLK pin.  
00000 ECLK rate = bus clock rate  
00001 ECLK rate = bus clock rate divided by 2  
00010 ECLK rate = bus clock rate divided by 3,...  
11111 ECLK rate = bus clock rate divided by 32 |

Write: Unimplemented

2.4 Functional Description

2.4.1 General

Each pin except PE0, PE1, and BKGD can act as general purpose I/O. In addition each pin can act as an output or input of a peripheral module.

2.4.2 Registers

A set of configuration registers is common to all ports with exception of the ATD port (Table 2-59). All registers can be written at any time, however a specific configuration might not become active.
For example selecting a pull-up device: This device does not become active while the port is used as a push-pull output.

1. Each cell represents one register with individual configuration bits

#### 2.4.2.1 Data register (PORTx, PTx)

This register holds the value driven out to the pin if the pin is used as a general purpose I/O.

Writing to this register has only an effect on the pin if the pin is used as general purpose output. When reading this address, the buffered state of the pin is returned if the associated data direction register bit is set to “0”.

If the data direction register bits are set to logic level “1”, the contents of the data register is returned. This is independent of any other configuration (Figure 2-64).

#### 2.4.2.2 Input register (PTIx)

This register is read-only and always returns the buffered state of the pin (Figure 2-64).

#### 2.4.2.3 Data direction register (DDRx)

This register defines whether the pin is used as an general purpose input or an output.

If a peripheral module controls the pin the contents of the data direction register is ignored (Figure 2-64).

Independent of the pin usage with a peripheral module this register determines the source of data when reading the associated data register address (2.4.2.1/2-101).

**NOTE**

Due to internal synchronization circuits, it can take up to 2 bus clock cycles until the correct value is read on port data or port input registers, when changing the data direction register.
2.4.2.4 Reduced drive register (RDRx)

If the pin is used as an output this register allows the configuration of the drive strength independent of the use with a peripheral module.

2.4.2.5 Pull device enable register (PERx)

This register turns on a pull-up or pull-down device on the related pins determined by the associated polarity select register (2.4.2.6/2-102).

The pull device becomes active only if the pin is used as an input or as a wired-or output. Some peripheral module only allow certain configurations of pull devices to become active. Refer to the respective bit descriptions.

2.4.2.6 Polarity select register (PPSx)

This register selects either a pull-up or pull-down device if enabled.

It becomes only active if the pin is used as an input. A pull-up device can be activated if the pin is used as a wired-or output.

2.4.2.7 Wired-or mode register (WOMx)

If the pin is used as an output this register turns off the active high drive. This allows wired-or type connections of outputs.
2.4.2.8 **Interrupt enable register (PIEx)**
If the pin is used as an interrupt input this register serves as a mask to the interrupt flag to enable/disable the interrupt.

2.4.2.9 **Interrupt flag register (PIFx)**
If the pin is used as an interrupt input this register holds the interrupt flag after a valid pin event.

2.4.2.10 **Module routing register (PTTRR)**
This register allows software re-configuration of the pinouts of the different package options for specific peripherals:
- PTTRR supports the re-routing of the PWM channels to alternative ports

2.4.3 **Pins and Ports**

**NOTE**
Please refer to the device pinout section to determine the pin availability in the different package options.

2.4.3.1 **BKGD pin**
The BKGD pin is associated with the BDM module.
During reset, the BKGD pin is used as MODC input.

2.4.3.2 **Port A, B**
Port A pins PA[7:0] and Port B pins PB[7:0] can be used for general purpose I/O.

2.4.3.3 **Port E**
Port E is associated with the free-running clock outputs ECLK, ECLKX2 and interrupt inputs IRQ and XIRQ.
Port E pins PE[6:5,3:2] can be used for either general purpose I/O or with the alternative functions.
Port E pin PE[7] can be used for either general purpose I/O or as the free-running clock ECLKX2 output running at the core clock rate.
Port E pin PE[4] can be used for either general purpose I/O or as the free-running clock ECLK output running at the bus clock rate or at the programmed divided clock rate.
Port E pin PE[1] can be used for either general purpose input or as the level- or falling edge-sensitive IRQ interrupt input. IRQ will be enabled by setting the IRQEN configuration bit (2.3.14/2-70) and clearing the I-bit in the CPU condition code register. It is inhibited at reset so this pin is initially configured as a simple input with a pull-up.
Port E pin PE[0] can be used for either general purpose input or as the level-sensitive XIRQ interrupt input. XIRQ can be enabled by clearing the X-bit in the CPU condition code register. It is inhibited at reset so this pin is initially configured as a high-impedance input with a pull-up.

2.4.3.4 Port T

This port is associated with TIM and PWM.
Port T pins PT[5:4,0] can be used for either general purpose I/O, or with the routed PWM or with the channels of the standard Timer subsystem.
Port T pins PT[7:6,3:1] can be used for either general purpose I/O, or with the channels of the standard Timer subsystem.

2.4.3.5 Port S

This port is associated with SCI.
Port S pins PS[1:0] can be used either for general purpose I/O, or with the SCI subsystem.
Port S pins PS[3:2] can be used for general purpose I/O.

2.4.3.6 Port M

This port is associated with CAN and SPI.
Port M pins PM[1:0] can be used for either general purpose I/O, or with the CAN subsystem.
Port M pins PM[5:2] can be used for general purpose I/O, or with the SPI subsystem.

2.4.3.7 Port P

This port is associated with the PWM.
Port P pins PP[7,5:0] can be used for either general purpose I/O with pin interrupt capability, or with the PWM subsystem.

2.4.3.8 Port J

Port J pins PJ[7:6,2:0] can be used for general purpose I/O with pin-interrupt capability.

2.4.3.9 Port AD

This port is associated with the ATD.
Port AD pins PAD[9:0] can be used for either general purpose I/O, or with the ATD subsystem.
2.4.4 Pin interrupts

Ports P and J offer pin interrupt capability. The interrupt enable as well as the sensitivity to rising or falling edges can be individually configured on per-pin basis. All bits/pins in a port share the same interrupt vector. Interrupts can be used with the pins configured as inputs or outputs.

An interrupt is generated when a bit in the port interrupt flag register and its corresponding port interrupt enable bit are both set. The pin interrupt feature is also capable to wake up the CPU when it is in STOP or WAIT mode.

A digital filter on each pin prevents pulses (Figure 2-66) shorter than a specified time from generating an interrupt. The minimum time varies over process conditions, temperature and voltage (Figure 2-65 and Table 2-60).

![Figure 2-65. Interrupt Glitch Filter on Port P and J (PPS=0)](image)

Table 2-60. Pulse Detection Criteria

<tr>
<td>Valid</td>
<td></td>
<td>t_{pulse} \geq 4</td>
<td>bus clocks</td>
</tr>
</tbody>
</table>

1. These values include the spread of the oscillator frequency over temperature, voltage and process.
A valid edge on an input is detected if 4 consecutive samples of a passive level are followed by 4 consecutive samples of an active level directly or indirectly.

The filters are continuously clocked by the bus clock in RUN and WAIT mode. In STOP mode the clock is generated by an RC-oscillator in the Port Integration Module. To maximize current saving the RC oscillator runs only if the following condition is true on any pin individually:

Sample count \(\leq 4\) and interrupt enabled (PIE=1) and interrupt flag not set (PIF=0).

### 2.5 Initialization Information

#### 2.5.1 Port Data and Data Direction Register writes

It is not recommended to write PORTx/PTx and DDRx in a word access. When changing the register pins from inputs to outputs, the data may have extra transitions during the write access. Initialize the port data register before enabling the outputs.

3.1 Introduction

The S12PMMC module controls the access to all internal memories and peripherals for the CPU12 and S12SBDM module. It regulates access priorities and determines the address mapping of the on-chip resources. Figure 3-1 shows a block diagram of the S12PMMC module.

3.1.2 Overview

The S12PMMC connects the CPU12’s and the S12SBDM’s bus interfaces to the MCU’s on-chip resources (memories and peripherals). It arbitrates the bus accesses and determines all of the MCU’s memory maps. Furthermore, the S12PMMC is responsible for constraining memory accesses on secured devices and for selecting the MCU’s functional mode.

3.1.3 Features

The main features of this block are:

- Paging capability to support a global 256 KByte memory address space
- Bus arbitration between the masters CPU12, S12SBDM to different resources.
- MCU operation mode control
- MCU security control
- Separate memory map schemes for each master CPU12, S12SBDM
- Generation of system reset when CPU12 accesses an unimplemented address (i.e., an address which does not belong to any of the on-chip modules) in single-chip modes

3.1.4 Modes of Operation

The S12PMMC selects the MCU’s functional mode. It also determines the devices behavior in secured and unsecured state.

3.1.4.1 Functional Modes

Two functional modes are implementes on devices of the S12I product family:

- Normal Single Chip (NS)
  The mode used for running applications.
- Special Single Chip Mode (SS)
  A debug mode which causes the device to enter BDM Active Mode after each reset. Peripherals may also provide special debug features in this mode.

3.1.4.2 Security

S12I devives can be secured to prohibit external access to the on-chip P-Flash. The S12PMMC module determines the access permissions to the on-chip memories in secured and unsecured state.

3.1.5 Block Diagram

Figure 3-1 shows a block diagram of the S12PMMC.
3.2 External Signal Description

The S12PMMC uses two external pins to determine the device's operating mode: RESET and MODC (Table 3-4) See Device User Guide (DUG) for the mapping of these signals to device pins.

<table>
<thead>
<tr>

**Figure 3-2. MMC Register Summary**

- Unimplemented or Reserved

---

**Figure 3-3. Mode Register (MODE)**

1. External signal (see Table 3-4).

---

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor
Read: Anytime.
Write: Only if a transition is allowed (see Figure 3-4).

The MODC bit of the MODE register is used to select the MCU’s operating mode.

### Table 3-5. MODE Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 MODC</td>
<td><strong>Mode Select Bit</strong> — This bit controls the current operating mode during RESET high (inactive). The external mode pin MODC determines the operating mode during RESET low (active). The state of the pin is registered into the respective register bit after the RESET signal goes inactive (see Figure 3-4). Write restrictions exist to disallow transitions between certain modes. Figure 3-4 illustrates all allowed mode changes. Attempting non-authorized transitions will not change the MODE bit, but it will block further writes to the register bit except in special modes. Write accesses to the MODE register are blocked when the device is secured.</td>
</tr>
</tbody>
</table>

![Diagram of Mode Transition](image)

#### 3.3.2.2 Direct Page Register (DIRECT)

Address: 0x0011

![Table of Direct Register](image)

**Figure 3-5. Direct Register (DIRECT)**

Read: Anytime
Write: anytime in special SS, wrir-one in NS.

This register determines the position of the 256 Byte direct page within the memory map. It is valid for both global and local mapping scheme.
3.3.2.3 Program Page Index Register (PPAGE)

Address: 0x0030

Read: Anytime
Write: Anytime

These four index bits are used to map 16KB blocks into the Flash page window located in the local (CPU or BDM) memory map from address 0x8000 to address 0xBFFF (see Figure 3-8). This supports accessing up to 256 KB of Flash (in the Global map) within the 64KB Local map. The PPAGE index register is effectively used to construct paged Flash addresses in the Local map format. The CPU has special access to read and write this register directly during execution of CALL and RTC instructions.

---

Table 3-6. DIRECT Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7–0 DP[15:8]</td>
<td>Direct Page Index Bits 15–8 — These bits are used by the CPU when performing accesses using the direct addressing mode. These register bits form bits [15:8] of the local address (see Figure 3-6).</td>
</tr>
</tbody>
</table>

---

Example 3-1. This example demonstrates usage of the Direct Addressing Mode

```
MOVB #$80,DIRECT ; Set DIRECT register to 0x80. Write once only.
; Global data accesses to the range 0xXX_80XX can be direct.
; Logical data accesses to the range 0x80XX are direct.

LDY <$00 ; Load the Y index register from 0x8000 (direct access).
; < operator forces direct access on some assemblers but in
; many cases assemblers are "direct page aware" and can
; automatically select direct mode.
```
3.4 Functional Description

The S12PMMC block performs several basic functions of the S12I sub-system operation: MCU operation modes, priority control, address mapping, select signal generation and access limitations for the system. Each aspect is described in the following subsections.

3.4.1 MCU Operating Modes

- Normal single chip mode
  This is the operation mode for running application code. There is no external bus in this mode.
- Special single chip mode

The fixed 16KB page from 0x0000 to 0x3FFF is the page number 0x0C. Parts of this page are covered by Registers, D-Flash and RAM space. See SoC Guide for details.

The fixed 16KB page from 0x4000–0x7FFF is the page number 0x0D.

The reset value of 0x0E ensures that there is linear Flash space available between addresses 0x0000 and 0xFFFF out of reset.

The fixed 16KB page from 0xC000-0xFFFF is the page number 0x0F.
This mode is generally used for debugging operation, boot-strapping or security related operations. The active background debug mode is in control of the CPU code execution and the BDM firmware is waiting for serial commands sent through the BKGD pin.

### 3.4.2 Memory Map Scheme

#### 3.4.2.1 CPU and BDM Memory Map Scheme

The BDM firmware lookup tables and BDM register memory locations share addresses with other modules; however they are not visible in the memory map during user’s code execution. The BDM memory resources are enabled only during the READ_BD and WRITE_BD access cycles to distinguish between accesses to the BDM memory area and accesses to the other modules. (Refer to BDM Block Guide for further details).

When the MCU enters active BDM mode, the BDM firmware lookup tables and the BDM registers become visible in the local memory map in the range 0xFF00-0xFFFF (global address 0x3_FF00 - 0x3_FFFF) and the CPU begins execution of firmware commands or the BDM begins execution of hardware commands. The resources which share memory space with the BDM module will not be visible in the memory map during active BDM mode.

Please note that after the MCU enters active BDM mode the BDM firmware lookup tables and the BDM registers will also be visible between addresses 0xBF00 and 0xBFFF if the PPAGE register contains value of 0x0F.

#### 3.4.2.1.1 Expansion of the Local Address Map

**Expansion of the CPU Local Address Map**

The program page index register in S12PMMC allows accessing up to 256KB of P-Flash in the global memory map by using the four index bits (PPAGE[3:0]) to page 16x16 KB blocks into the program page window located from address 0x8000 to address 0xBFFF in the local CPU memory map.

The page value for the program page window is stored in the PPAGE register. The value of the PPAGE register can be read or written by normal memory accesses as well as by the CALL and RTC instructions (see Section 3.6.1, “CALL and RTC Instructions).

Control registers, vector space and parts of the on-chip memories are located in unpaged portions of the 64KB local CPU address space.

The starting address of an interrupt service routine must be located in unpaged memory unless the user is certain that the PPAGE register will be set to the appropriate value when the service routine is called. However an interrupt service routine can call other routines that are in paged memory. The upper 16KB block of the local CPU memory space (0xC000–0xFFFF) is unpaged. It is recommended that all reset and interrupt vectors point to locations in this area or to the other unmapped pages sections of the local CPU memory map.
Expansion of the BDM Local Address Map

PPAGE and BDMPPR register is also used for the expansion of the BDM local address to the global address. These registers can be read and written by the BDM.

The BDM expansion scheme is the same as the CPU expansion scheme.

The four BDMPPR Program Page index bits allow access to the full 256KB address map that can be accessed with 18 address bits.

The BDM program page index register (BDMPPR) is used only when the feature is enabled in BDM and, in the case the CPU is executing a firmware command which uses CPU instructions, or by a BDM hardware commands. See the BDM Block Guide for further details. (see Figure 3-9).

![Figure 3-9. BDMPPR Address Mapping](image-url)
Figure 3-10. Local to Global Address Mapping
3.5 Implemented Memory in the System Memory Architecture

Each memory can be implemented in its maximum allowed size. But some devices have been defined for smaller sizes, which means less implemented pages. All non implemented pages are called unimplemented areas.

- Registers has a fixed size of 1KB, accessible via xbus0.
- SRAM has a maximum size of 11KB, accessible via xbus0.
- D-Flash has a fixed size of 4KB accessible via xbus0.
- P-Flash has a maximum size of 224KB, accessible via xbus0.
- NVM resources (IFR) including D-Flash have maximum size of 16KB (PPAGE 0x01).

3.5.0.1 Implemented Memory Map

The global memory spaces reserved for the internal resources (RAM, D-Flash, and P-Flash) are not determined by the MMC module. Size of the individual internal resources are however fixed in the design of the device cannot be changed by the user. Please refer to the SoC Guide for further details. Figure 3-11 and Table 3-8 show the memory spaces occupied by the on-chip resources. Please note that the memory spaces have fixed top addresses.

### Table 3-8. Global Implemented Memory Space

<table>
<thead>
<tr>
<th>Internal Resource</th>
<th>Bottom Address</th>
<th>Top Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registers</td>
<td>0x0_0000</td>
<td>0x0_03FF</td>
</tr>
<tr>
<td>System RAM</td>
<td>RAM_LOW = 0x0_4000 minus RAMSIZE(1)</td>
<td>0x0_3FFF</td>
</tr>
<tr>
<td>D-Flash</td>
<td>0x0_4400</td>
<td>0x0_53FF</td>
</tr>
<tr>
<td>P-Flash</td>
<td>PF_LOW = 0x4_0000 minus FLASHSIZE(2)</td>
<td>0x3_FFFF</td>
</tr>
</tbody>
</table>

1. RAMSIZE is the hexadecimal value of RAM SIZE in bytes
2. FLASHSIZE is the hexadecimal value of FLASH SIZE in bytes

In single-chip modes accesses by the CPU12 (except for firmware commands) to any of the unimplemented areas (see Figure 3-11) will result in an illegal access reset (system reset). BDM accesses to the unimplemented areas are allowed but the data will be undefined.

No misaligned word access from the BDM module will occur; these accesses are blocked in the BDM module (Refer to BDM Block Guide).
Figure 3-11. Implemented Global Address Mapping
3.5.1 Chip Bus Control

The S12PMMC controls the address buses and the data buses that interface the bus masters (CPU12, S12SBDM) with the rest of the system (master buses). In addition the MMC handles all CPU read data bus swapping operations. All internal resources are connected to specific target buses (see Figure 3-12).

![Figure 3-12. S12I platform](Image)

3.5.1.1 Master Bus Prioritization regarding Access Conflicts on Target Buses

The arbitration scheme allows only one master to be connected to a target at any given time. The following rules apply when prioritizing accesses from different masters to the same target bus:

- CPU12 always has priority over BDM.
- BDM has priority over CPU12 when its access is stalled for more than 128 cycles. In the later case the CPU will be stalled after finishing the current operation and the BDM will gain access to the bus.

3.5.2 Interrupts

The MMC does not generate any interrupts.
3.6 Initialization/Application Information

3.6.1 CALL and RTC Instructions

CALL and RTC instructions are uninterruptable CPU instructions that automate page switching in the program page window. The CALL instruction is similar to the JSR instruction, but the subroutine that is called can be located anywhere in the local address space or in any Flash or ROM page visible through the program page window. The CALL instruction calculates and stacks a return address, stacks the current PPAGE value and writes a new instruction-supplied value to the PPAGE register. The PPAGE value controls which of the 256 possible pages is visible through the 16 Kbyte program page window in the 64 Kbyte local CPU memory map. Execution then begins at the address of the called subroutine.

During the execution of the CALL instruction, the CPU performs the following steps:

1. Writes the current PPAGE value into an internal temporary register and writes the new instruction-supplied PPAGE value into the PPAGE register
2. Calculates the address of the next instruction after the CALL instruction (the return address) and pushes this 16-bit value onto the stack
3. Pushes the temporarily stored PPAGE value onto the stack
4. Calculates the effective address of the subroutine, refills the queue and begins execution at the new address

This sequence is uninterruptable. There is no need to inhibit interrupts during the CALL instruction execution. A CALL instruction can be performed from any address to any other address in the local CPU memory space.

The PPAGE value supplied by the instruction is part of the effective address of the CPU. For all addressing mode variations (except indexed-indirect modes) the new page value is provided by an immediate operand in the instruction. In indexed-indirect variations of the CALL instruction a pointer specifies memory locations where the new page value and the address of the called subroutine are stored. Using indirect addressing for both the new page value and the address within the page allows usage of values calculated at run time rather than immediate values that must be known at the time of assembly.

The RTC instruction terminates subroutines invoked by a CALL instruction. The RTC instruction unstacks the PPAGE value and the return address and refills the queue. Execution resumes with the next instruction after the CALL instruction.

During the execution of an RTC instruction the CPU performs the following steps:

1. Pulls the previously stored PPAGE value from the stack
2. Pulls the 16-bit return address from the stack and loads it into the PC
3. Writes the PPAGE value into the PPAGE register
4. Refills the queue and resumes execution at the return address

This sequence is uninterruptable. The RTC can be executed from anywhere in the local CPU memory space.

The CALL and RTC instructions behave like JSR and RTS instruction, they however require more execution cycles. Usage of JSR/RTS instructions is therefore recommended when possible and
CALL/RTC instructions should only be used when needed. The JSR and RTS instructions can be used to access subroutines that are already present in the local CPU memory map (i.e. in the same page in the program memory page window for example). However calling a function located in a different page requires usage of the CALL instruction. The function must be terminated by the RTC instruction. Because the RTC instruction restores contents of the PPAGE register from the stack, functions terminated with the RTC instruction must be called using the CALL instruction even when the correct page is already present in the memory map. This is to make sure that the correct PPAGE value will be present on stack at the time of the RTC instruction execution.
Chapter 4
Interrupt Module (S12SINTV1)

4.1 Introduction

The INT module decodes the priority of all system exception requests and provides the applicable vector for processing the exception to the CPU. The INT module supports:

- I bit and X bit maskable interrupt requests
- A non-maskable unimplemented op-code trap
- A non-maskable software interrupt (SWI) or background debug mode request
- Three system reset vector requests
- A spurious interrupt vector

Each of the I bit maskable interrupt requests is assigned to a fixed priority level.

4.1.1 Glossary

Table 4-2 contains terms and abbreviations used in the document.

<table>
<thead>
<tr>
<th>Term</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCR</td>
<td>Condition Code Register (in the CPU)</td>
</tr>
<tr>
<td>ISR</td>
<td>Interrupt Service Routine</td>
</tr>
<tr>
<td>MCU</td>
<td>Micro-Controller Unit</td>
</tr>
</tbody>
</table>

4.1.2 Features

- Interrupt vector base register (IVBR)
- One spurious interrupt vector (at address vector base\(^1 + 0x0080\)).
Interrupt Module (S12SINTV1)

- 2–58 I bit maskable interrupt vector requests (at addresses vector base + 0x0082–0x00F2).
- I bit maskable interrupts can be nested.
- One X bit maskable interrupt vector request (at address vector base + 0x00F4).
- One non-maskable software interrupt request (SWI) or background debug mode vector request (at address vector base + 0x00F6).
- One non-maskable unimplemented op-code trap (TRAP) vector (at address vector base + 0x00F8).
- Three system reset vectors (at addresses 0xFFFFA–0xFFFFE).
- Determines the highest priority interrupt vector requests, drives the vector to the bus on CPU request
- Wakes up the system from stop or wait mode when an appropriate interrupt request occurs.

4.1.3 Modes of Operation

- Run mode
  This is the basic mode of operation.
- Wait mode
  In wait mode, the clock to the INT module is disabled. The INT module is however capable of waking-up the CPU from wait mode if an interrupt occurs. Please refer to Section 4.5.3, “Wake Up from Stop or Wait Mode” for details.
- Stop Mode
  In stop mode, the clock to the INT module is disabled. The INT module is however capable of waking-up the CPU from stop mode if an interrupt occurs. Please refer to Section 4.5.3, “Wake Up from Stop or Wait Mode” for details.
- Freeze mode (BDM active)
  In freeze mode (BDM active), the interrupt vector base register is overridden internally. Please refer to Section 4.3.1.1, “Interrupt Vector Base Register (IVBR)” for details.

4.1.4 Block Diagram

Figure 4-1 shows a block diagram of the INT module.

1. The vector base is a 16-bit address which is accumulated from the contents of the interrupt vector base register (IVBR, used as upper byte) and 0x00 (used as lower byte).
4.2 External Signal Description

The INT module has no external signals.

4.3 Memory Map and Register Definition

This section provides a detailed description of all registers accessible in the INT module.

4.3.1 Register Descriptions

This section describes in address order all the INT registers and their individual bits.

4.3.1.1 Interrupt Vector Base Register (IVBR)

</tbody>
</table>

Read: Anytime
Write: Anytime
4.4 Functional Description

The INT module processes all exception requests to be serviced by the CPU module. These exceptions include interrupt vector requests and reset vector requests. Each of these exception types and their overall priority level is discussed in the subsections below.

4.4.1 S12S Exception Requests

The CPU handles both reset requests and interrupt requests. A priority decoder is used to evaluate the priority of pending interrupt requests.

4.4.2 Interrupt Prioritization

The INT module contains a priority decoder to determine the priority for all interrupt requests pending for the CPU. If more than one interrupt request is pending, the interrupt request with the higher vector address wins the prioritization.

The following conditions must be met for an I bit maskable interrupt request to be processed.

1. The local interrupt enabled bit in the peripheral module must be set.
2. The I bit in the condition code register (CCR) of the CPU must be cleared.
3. There is no SWI, TRAP, or X bit maskable request pending.

NOTE

All non I bit maskable interrupt requests always have higher priority than the I bit maskable interrupt requests. If the X bit in the CCR is cleared, it is possible to interrupt an I bit maskable interrupt by an X bit maskable interrupt. It is possible to nest non maskable interrupt requests, for example by nesting SWI or TRAP calls.

Since an interrupt vector is only supplied at the time when the CPU requests it, it is possible that a higher priority interrupt request could override the original interrupt request that caused the CPU to request the vector. In this case, the CPU will receive the highest priority vector and the system will process this interrupt request first, before the original interrupt request is processed.

### Table 4-3. IVBR Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7–0 IVB_ADDR[7:0]</td>
<td><strong>Interrupt Vector Base Address Bits</strong> — These bits represent the upper byte of all vector addresses. Out of reset these bits are set to 0xFF (that means vectors are located at 0xFF80–0xFFFE) to ensure compatibility to HCS12.</td>
</tr>
<tr>
<td><strong>Note:</strong> A system reset will initialize the interrupt vector base register with “0xFF” before it is used to determine the reset vector address. Therefore, changing the IVBR has no effect on the location of the three reset vectors (0xFFA–0xFFE).</td>
<td></td>
</tr>
<tr>
<td><strong>Note:</strong> If the BDM is active (that means the CPU is in the process of executing BDM firmware code), the contents of IVBR are ignored and the upper byte of the vector address is fixed as “0xFF”. This is done to enable handling of all non-maskable interrupts in the BDM firmware.</td>
<td></td>
</tr>
</tbody>
</table>
If the interrupt source is unknown (for example, in the case where an interrupt request becomes inactive after the interrupt has been recognized, but prior to the CPU vector request), the vector address supplied to the CPU will default to that of the spurious interrupt vector.

**NOTE**

Care must be taken to ensure that all interrupt requests remain active until the system begins execution of the applicable service routine; otherwise, the exception request may not get processed at all or the result may be a spurious interrupt request (vector at address (vector base + 0x0080)).

### 4.4.3 Reset Exception Requests

The INT module supports three system reset exception request types (please refer to the Clock and Reset generator module for details):

1. Pin reset, power-on reset or illegal address reset, low voltage reset (if applicable)
2. Clock monitor reset request
3. COP watchdog reset request

### 4.4.4 Exception Priority

The priority (from highest to lowest) and address of all exception vectors issued by the INT module upon request by the CPU is shown in Table 4-4.

<table>
<thead>
<tr>
<th>Vector Address(1)</th>
<th>Source</th>

</tr>
<tr>
<td>(Vector base + 0x0080)</td>
<td>Spurious interrupt</td>
</tr>
</tbody>
</table>

1. 16 bits vector address based
2. D2D error interrupt on MCUs featuring a D2D initiator module, otherwise XIRQ pin interrupt
3. D2D interrupt on MCUs featuring a D2D initiator module, otherwise IRQ pin interrupt
4.5  Initialization/Application Information

4.5.1  Initialization

After system reset, software should:

1. Initialize the interrupt vector base register if the interrupt vector table is not located at the default location (0xFF80–0xFFF9).
2. Enable I bit maskable interrupts by clearing the I bit in the CCR.
3. Enable the X bit maskable interrupt by clearing the X bit in the CCR.

4.5.2  Interrupt Nesting

The interrupt request scheme makes it possible to nest I bit maskable interrupt requests handled by the CPU.

- I bit maskable interrupt requests can be interrupted by an interrupt request with a higher priority.

I bit maskable interrupt requests cannot be interrupted by other I bit maskable interrupt requests per default. In order to make an interrupt service routine (ISR) interruptible, the ISR must explicitly clear the I bit in the CCR (CLI). After clearing the I bit, other I bit maskable interrupt requests can interrupt the current ISR.

An ISR of an interruptible I bit maskable interrupt request could basically look like this:

1. Service interrupt, that is clear interrupt flags, copy data, etc.
2. Clear I bit in the CCR by executing the instruction CLI (thus allowing other I bit maskable interrupt requests)
3. Process data
4. Return from interrupt by executing the instruction RTI

4.5.3  Wake Up from Stop or Wait Mode

4.5.3.1  CPU Wake Up from Stop or Wait Mode

Every I bit maskable interrupt request is capable of waking the MCU from stop or wait mode. To determine whether an I bit maskable interrupts is qualified to wake-up the CPU or not, the same conditions as in normal run mode are applied during stop or wait mode:

- If the I bit in the CCR is set, all I bit maskable interrupts are masked from waking-up the MCU.

Since there are no clocks running in stop mode, only interrupts which can be asserted asynchronously can wake-up the MCU from stop mode.

The X bit maskable interrupt request can wake up the MCU from stop or wait mode at anytime, even if the X bit in CCR is set1.

---

1. The capability of the XIRQ pin to wake-up the MCU with the X bit set may not be available if, for example, the XIRQ pin is shared with other peripheral modules on the device. Please refer to the Device section of the MCU reference manual for details.
If the X bit maskable interrupt request is used to wake-up the MCU with the X bit in the CCR set, the associated ISR is not called. The CPU then resumes program execution with the instruction following the WAI or STOP instruction. This feature works following the same rules like any interrupt request, that is care must be taken that the X interrupt request used for wake-up remains active at least until the system begins execution of the instruction following the WAI or STOP instruction; otherwise, wake-up may not occur.

5.1 Introduction

This section describes the functionality of the background debug module (BDM) sub-block of the HCS12S core platform.

The background debug module (BDM) sub-block is a single-wire, background debug system implemented in on-chip hardware for minimal CPU intervention. All interfacing with the BDM is done via the BKGD pin.

The BDM has enhanced capability for maintaining synchronization between the target and host while allowing more flexibility in clock rates. This includes a sync signal to determine the communication rate and a handshake signal to indicate when an operation is complete. The system is backwards compatible to the BDM of the S12 family with the following exceptions:

- TAGGO command not supported by S12SBDM
- External instruction tagging feature is part of the DBG module
- S12SBDM register map and register content modified
- Family ID readable from BDM ROM at global address 0x3_FF0F in active BDM (value for devices with HCS12S core is 0xC2)
- Clock switch removed from BDM (CLKSW bit removed from BDMSTS register)
5.1.1 Features

The BDM includes these distinctive features:

- Single-wire communication with host development system
- Enhanced capability for allowing more flexibility in clock rates
- SYNC command to determine communication rate
- GO_UNTIL command
- Hardware handshake protocol to increase the performance of the serial communication
- Active out of reset in special single chip mode
- Nine hardware commands using free cycles, if available, for minimal CPU intervention
- Hardware commands not requiring active BDM
- 14 firmware commands execute from the standard BDM firmware lookup table
- Software control of BDM operation during wait mode
- When secured, hardware commands are allowed to access the register space in special single chip mode, if the Flash erase tests fail.
- Family ID readable from BDM ROM at global address 0x3_FF0F in active BDM (value for devices with HCS12S core is 0xC2)
- BDM hardware commands are operational until system stop mode is entered

5.1.2 Modes of Operation

BDM is available in all operating modes but must be enabled before firmware commands are executed. Some systems may have a control bit that allows suspending the function during background debug mode.

5.1.2.1 Regular Run Modes

All of these operations refer to the part in run mode and not being secured. The BDM does not provide controls to conserve power during run mode.

- Normal modes
  General operation of the BDM is available and operates the same in all normal modes.
- Special single chip mode
  In special single chip mode, background operation is enabled and active out of reset. This allows programming a system with blank memory.

5.1.2.2 Secure Mode Operation

If the device is in secure mode, the operation of the BDM is reduced to a small subset of its regular run mode operation. Secure operation prevents access to Flash other than allowing erasure. For more information please see Section 5.4.1, “Security”.
5.1.2.3 Low-Power Modes

The BDM can be used until stop mode is entered. When CPU is in wait mode all BDM firmware commands as well as the hardware BACKGROUND command cannot be used and are ignored. In this case the CPU can not enter BDM active mode, and only hardware read and write commands are available. Also the CPU can not enter a low power mode (stop or wait) during BDM active mode.

In stop mode the BDM clocks are stopped. When BDM clocks are disabled and stop mode is exited, the BDM clocks will restart and BDM will have a soft reset (clearing the instruction register, any command in progress and disable the ACK function). The BDM is now ready to receive a new command.

5.1.3 Block Diagram

A block diagram of the BDM is shown in Figure 5-1.

![Figure 5-1. BDM Block Diagram]

5.2 External Signal Description

A single-wire interface pin called the background debug interface (BKGD) pin is used to communicate with the BDM system. During reset, this pin is a mode select input which selects between normal and special modes of operation. After reset, this pin becomes the dedicated serial interface pin for the background debug mode. The communication rate of this pin is based on the settings for the VCO clock (CPMUSYNR). The BDM clock frequency is always VCO clock frequency divided by 8. After reset the BDM clock is based on the reset values of the CPMUSYNR register (4 MHz). When modifying the VCO

**Figure 5-3. BDM Status Register (BDMSTS)**

1. **ENBDM** is read as 1 by a debugging environment in special single chip mode when the device is not secured or secured but fully erased (Flash). This is because the ENBDM bit is set by the standard BDM firmware before a BDM command can be fully transmitted and executed.

2. **UNSEC** is read as 1 by a debugging environment in special single chip mode when the device is secured and fully erased, else it is 0 and can only be read if not secure (see also bit description).
Read: All modes through BDM operation when not secured

Write: All modes through BDM operation when not secured, but subject to the following:
- ENBDM should only be set via a BDM hardware command if the BDM firmware commands are needed. (This does not apply in special single chip mode).
- BDMACT can only be set by BDM hardware upon entry into BDM. It can only be cleared by the standard BDM firmware lookup table upon exit from BDM active mode.
- All other bits, while writable via BDM hardware or standard BDM firmware write commands, should only be altered by the BDM hardware or standard firmware lookup table as part of BDM command execution.

Figure 5-5. BDM Program Page Register (BDMPPR)

Read: All modes through BDM operation when not secured
Write: All modes through BDM operation when not secured

NOTE

When BDM is made active, the CPU stores the content of its CCR register in the BDMCCR register. However, out of special single-chip reset, the BDMCCR is set to 0xD8 and not 0xD0 which is the reset value of the CCR register in this CPU mode. Out of reset in all other modes the BDMCCR register is read zero.

When entering background debug mode, the BDM CCR holding register is used to save the condition code register of the user’s program. It is also used for temporary storage in the standard BDM firmware mode. The BDM CCR holding register can be written to modify the CCR value.
5.3.3 Family ID Assignment

The family ID is an 8-bit value located in the BDM ROM in active BDM (at global address: 0x3_FF0F). The read-only value is a unique family ID which is 0xC2 for devices with an HCS12S core.

5.4 Functional Description

The BDM receives and executes commands from a host via a single wire serial interface. There are two types of BDM commands: hardware and firmware commands.

Hardware commands are used to read and write target system memory locations and to enter active background debug mode, see Section 5.4.3, “BDM Hardware Commands”. Target system memory includes all memory that is accessible by the CPU.

Firmware commands are used to read and write CPU resources and to exit from active background debug mode, see Section 5.4.4, “Standard BDM Firmware Commands”. The CPU resources referred to are the accumulator (D), X index register (X), Y index register (Y), stack pointer (SP), and program counter (PC).

Hardware commands can be executed at any time and in any mode excluding a few exceptions as highlighted (see Section 5.4.3, “BDM Hardware Commands”) and in secure mode (see Section 5.4.1, “Security”). BDM firmware commands can only be executed when the system is not secure and is in active background debug mode (BDM).

5.4.1 Security

If the user resets into special single chip mode with the system secured, a secured mode BDM firmware lookup table is brought into the map overlapping a portion of the standard BDM firmware lookup table. The secure BDM firmware verifies that the on-chip Flash EEPROM are erased. This being the case, the UNSEC and ENBDM bit will get set. The BDM program jumps to the start of the standard BDM firmware and the secured mode BDM firmware is turned off and all BDM commands are allowed. If the Flash does not verify as erased, the BDM firmware sets the ENBDM bit, without asserting UNSEC, and the firmware enters a loop. This causes the BDM hardware commands to become enabled, but does not enable the firmware commands. This allows the BDM hardware to be used to erase the Flash.

BDM operation is not possible in any other mode than special single chip mode when the device is secured. The device can only be unsecured via BDM serial interface in special single chip mode. For more information regarding security, please see the S12S_9SEC Block Guide.

5.4.2 Enabling and Activating BDM

The system must be in active BDM to execute standard BDM firmware commands. BDM can be activated only after being enabled. BDM is enabled by setting the ENBDM bit in the BDM status (BDMSTS) register. The ENBDM bit is set by writing to the BDM status (BDMSTS) register, via the single-wire interface, using a hardware command such as WRITE_BD_BYTE.

After being enabled, BDM is activated by one of the following:

- Hardware BACKGROUND command

1. BDM is enabled and active immediately out of special single-chip reset.
• CPU BGND instruction
• Breakpoint force or tag mechanism

When BDM is activated, the CPU finishes executing the current instruction and then begins executing the firmware in the standard BDM firmware lookup table. When BDM is activated by a breakpoint, the type of breakpoint used determines if BDM becomes active before or after execution of the next instruction.

**NOTE**

If an attempt is made to activate BDM before being enabled, the CPU resumes normal instruction execution after a brief delay. If BDM is not enabled, any hardware BACKGROUND commands issued are ignored by the BDM and the CPU is not delayed.

In active BDM, the BDM registers and standard BDM firmware lookup table are mapped to addresses 0x3_FF00 to 0x3_FFFF. BDM registers are mapped to addresses 0x3_FF00 to 0x3_FF0B. The BDM uses these registers which are readable anytime by the BDM. However, these registers are not readable by user programs.

When BDM is activated while CPU executes code overlapping with BDM firmware space the saved program counter (PC) will be auto incremented by one from the BDM firmware, no matter what caused the entry into BDM active mode (BGND instruction, BACKGROUND command or breakpoints). In such a case the PC must be set to the next valid address via a WRITE_PC command before executing the GO command.

### 5.4.3 BDM Hardware Commands

Hardware commands are used to read and write target system memory locations and to enter active background debug mode. Target system memory includes all memory that is accessible by the CPU such as on-chip RAM, Flash, I/O and control registers.

Hardware commands are executed with minimal or no CPU intervention and do not require the system to be in active BDM for execution, although, they can still be executed in this mode. When executing a hardware command, the BDM sub-block waits for a free bus cycle so that the background access does not disturb the running application program. If a free cycle is not found within 128 clock cycles, the CPU is momentarily frozen so that the BDM can steal a cycle. When the BDM finds a free cycle, the operation does not intrude on normal CPU operation provided that it can be completed in a single cycle. However, if an operation requires multiple cycles the CPU is frozen until the operation is complete, even though the BDM found a free cycle.

The BDM hardware commands are listed in Table 5-4.

The READ_BD and WRITE_BD commands allow access to the BDM register locations. These locations are not normally in the system memory map but share addresses with the application in memory. To distinguish between physical memory locations that share the same address, BDM memory resources are

1. This method is provided by the S12S_DBG module.
enabled just for the READ_BD and WRITE_BD access cycle. This allows the BDM to access BDM locations unobtrusively, even if the addresses conflict with the application memory map.

<td>16-bit address 16-bit data in. Write to memory with standard BDM firmware lookup table out of map. Must be aligned access.</td>
</tr>
</tbody>
</table>

**NOTE:**
If enabled, ACK will occur when data is ready for transmission for all BDM READ commands and will occur after the write is complete for all BDM WRITE commands.

### 5.4.4 Standard BDM Firmware Commands

BDM firmware commands are used to access and manipulate CPU resources. The system must be in active BDM to execute standard BDM firmware commands, see Section 5.4.2, “Enabling and Activating BDM”. Normal instruction execution is suspended while the CPU executes the firmware located in the standard BDM firmware lookup table. The hardware command BACKGROUND is the usual way to activate BDM.

As the system enters active BDM, the standard BDM firmware lookup table and BDM registers become visible in the on-chip memory map at 0x3_FF00–0x3_FFFF, and the CPU begins executing the standard BDM firmware. The standard BDM firmware watches for serial commands and executes them as they are received.

The firmware commands are shown in Table 5-5.
5.4.5 BDM Command Structure

Hardware and firmware BDM commands start with an 8-bit opcode followed by a 16-bit address and/or a 16-bit data word, depending on the command. All the read commands return 16 bits of data despite the byte or word implication in the command name.

8-bit reads return 16-bits of data, only one byte of which contains valid data. If reading an even address, the valid data will appear in the MSB. If reading an odd address, the valid data will appear in the LSB.

16-bit misaligned reads and writes are generally not allowed. If attempted by BDM hardware command, the BDM ignores the least significant bit of the address and assumes an even address from the remaining bits.
For hardware data read commands, the external host must wait at least 150 bus clock cycles after sending the address before attempting to obtain the read data. This is to be certain that valid data is available in the BDM shift register, ready to be shifted out. For hardware write commands, the external host must wait 150 bus clock cycles after sending the data to be written before attempting to send a new command. This is to avoid disturbing the BDM shift register before the write has been completed. The 150 bus clock cycle delay in both cases includes the maximum 128 cycle delay that can be incurred as the BDM waits for a free cycle before stealing a cycle.

For BDM firmware read commands, the external host should wait at least 48 bus clock cycles after sending the command opcode and before attempting to obtain the read data. The 48 cycle wait allows enough time for the requested data to be made available in the BDM shift register, ready to be shifted out.

For BDM firmware write commands, the external host must wait 36 bus clock cycles after sending the data to be written before attempting to send a new command. This is to avoid disturbing the BDM shift register before the write has been completed.

The external host should wait for at least 76 bus clock cycles after a TRACE1 or GO command before starting any new serial command. This is to allow the CPU to exit gracefully from the standard BDM firmware lookup table and resume execution of the user code. Disturbing the BDM shift register prematurely may adversely affect the exit from the standard BDM firmware lookup table.

**NOTE**

If the bus rate of the target processor is unknown or could be changing, it is recommended that the ACK (acknowledge function) is used to indicate when an operation is complete. When using ACK, the delay times are automated.

Figure 5-6 represents the BDM command structure. The command blocks illustrate a series of eight bit times starting with a falling edge. The bar across the top of the blocks indicates that the BKGD line idles in the high state. The time for an 8-bit command is $8 \times 16$ target clock cycles.\(^1\)

---

1. Target clock cycles are cycles measured using the target MCU’s serial clock rate. See Section 5.4.6, “BDM Serial Interface” and Section 5.3.2.1, “BDM Status Register (BDMSTS)” for information on how serial clock rate is selected.
5.4.6 BDM Serial Interface

The BDM communicates with external devices serially via the BKGD pin. During reset, this pin is a mode select input which selects between normal and special modes of operation. After reset, this pin becomes the dedicated serial interface pin for the BDM.

The BDM serial interface is timed based on the VCO clock (please refer to the CPMU Block Guide for more details), which gets divided by 8. This clock will be referred to as the target clock in the following explanation.

The BDM serial interface uses a clocking scheme in which the external host generates a falling edge on the BKGD pin to indicate the start of each bit time. This falling edge is sent for every bit whether data is transmitted or received. Data is transferred most significant bit (MSB) first at 16 target clock cycles per bit. The interface times out if 512 clock cycles occur between falling edges from the host.

The BKGD pin is a pseudo open-drain pin and has an weak on-chip active pull-up that is enabled at all times. It is assumed that there is an external pull-up and that drivers connected to BKGD do not typically drive the high level. Since R-C rise time could be unacceptably long, the target system and host provide brief driven-high (speedup) pulses to drive BKGD to a logic 1. The source of this speedup pulse is the host for transmit cases and the target for receive cases.

The timing for host-to-target is shown in Figure 5-7 and that of target-to-host in Figure 5-8 and Figure 5-9. All four cases begin when the host drives the BKGD pin low to generate a falling edge. Since the host and target are operating from separate clocks, it can take the target system up to one full clock cycle to recognize this edge. The target measures delays from this perceived start of the bit time while the host measures delays from the point it actually drove BKGD low to start the bit up to one target clock cycle.
earlier. Synchronization between the host and target is established in this manner at the start of every bit time.

**Figure 5-7** shows an external host transmitting a logic 1 and transmitting a logic 0 to the BKGD pin of a target system. The host is asynchronous to the target, so there is up to a one clock-cycle delay from the host-generated falling edge to where the target recognizes this edge as the beginning of the bit time. Ten target clock cycles later, the target senses the bit level on the BKGD pin. Internal glitch detect logic requires the pin be driven high no later that eight target clock cycles after the falling edge for a logic 1 transmission.

Since the host drives the high speedup pulses in these two cases, the rising edges look like digitally driven signals.

![Diagram of BDM Host-to-Target Serial Bit Timing](image)

**Figure 5-7. BDM Host-to-Target Serial Bit Timing**

The receive cases are more complicated. **Figure 5-8** shows the host receiving a logic 1 from the target system. Since the host is asynchronous to the target, there is up to one clock-cycle delay from the host-generated falling edge on BKGD to the perceived start of the bit time in the target. The host holds the BKGD pin low long enough for the target to recognize it (at least two target clock cycles). The host must release the low drive before the target drives a brief high speedup pulse seven target clock cycles after the perceived start of the bit time. The host should sample the bit level about 10 target clock cycles after it started the bit time.
Figure 5-8. BDM Target-to-Host Serial Bit Timing (Logic 1)

Figure 5-9 shows the host receiving a logic 0 from the target. Since the host is asynchronous to the target, there is up to a one clock-cycle delay from the host-generated falling edge on BKGD to the start of the bit time as perceived by the target. The host initiates the bit time but the target finishes it. Since the target wants the host to receive a logic 0, it drives the BKGD pin low for 13 target clock cycles then briefly drives it high to speed up the rising edge. The host samples the bit level about 10 target clock cycles after starting the bit time.

Figure 5-9. BDM Target-to-Host Serial Bit Timing (Logic 0)
5.4.7 Serial Interface Hardware Handshake Protocol

BDM commands that require CPU execution are ultimately treated at the MCU bus rate. Since the BDM clock source can be modified when changing the settings for the VCO frequency (CPMUSYNR), it is very helpful to provide a handshake protocol in which the host could determine when an issued command is executed by the CPU. The BDM clock frequency is always VCO frequency divided by 8. The alternative is to always wait the amount of time equal to the appropriate number of cycles at the slowest possible rate the clock could be running. This sub-section will describe the hardware handshake protocol.

The hardware handshake protocol signals to the host controller when an issued command was successfully executed by the target. This protocol is implemented by a 16 serial clock cycle low pulse followed by a brief speedup pulse in the BKGD pin. This pulse is generated by the target MCU when a command, issued by the host, has been successfully executed (see Figure 5-10). This pulse is referred to as the ACK pulse. After the ACK pulse has finished: the host can start the bit retrieval if the last issued command was a read command, or start a new command if the last command was a write command or a control command (BACKGROUND, GO, GO_UNTIL or TRACE1). The ACK pulse is not issued earlier than 32 serial clock cycles after the BDM command was issued. The end of the BDM command is assumed to be the 16th tick of the last bit. This minimum delay assures enough time for the host to perceive the ACK pulse. Note also that, there is no upper limit for the delay between the command and the related ACK pulse, since the command execution depends upon the CPU bus, which in some cases could be very slow due to long accesses taking place. This protocol allows a great flexibility for the POD designers, since it does not rely on any accurate time measurement or short response time to any event in the serial communication.

If the ACK pulse was issued by the target, the host assumes the previous command was executed. If the CPU enters wait or stop prior to executing a hardware command, the ACK pulse will not be issued meaning that the BDM command was not executed. After entering wait or stop mode, the BDM command is no longer pending.
Figure 5-11 shows the ACK handshake protocol in a command level timing diagram. The READ_BYTE instruction is used as an example. First, the 8-bit instruction opcode is sent by the host, followed by the address of the memory location to be read. The target BDM decodes the instruction. A bus cycle is grabbed (free or stolen) by the BDM and it executes the READ_BYTE operation. Having retrieved the data, the BDM issues an ACK pulse to the host controller, indicating that the addressed byte is ready to be retrieved. After detecting the ACK pulse, the host initiates the byte retrieval process. Note that data is sent in the form of a word and the host needs to determine which is the appropriate byte based on whether the address was odd or even.

Differently from the normal bit transfer (where the host initiates the transmission), the serial interface ACK handshake pulse is initiated by the target MCU by issuing a negative edge in the BKGD pin. The hardware handshake protocol in Figure 5-10 specifies the timing when the BKGD pin is being driven, so the host should follow this timing constraint in order to avoid the risk of an electrical conflict in the BKGD pin.

**NOTE**

The only place the BKGD pin can have an electrical conflict is when one side is driving low and the other side is issuing a speedup pulse (high). Other “highs” are pulled rather than driven. However, at low rates the time of the speedup pulse can become lengthy and so the potential conflict time becomes longer as well.

The ACK handshake protocol does not support nested ACK pulses. If a BDM command is not acknowledged by an ACK pulse, the host needs to abort the pending command first in order to be able to issue a new BDM command. When the CPU enters wait or stop while the host issues a hardware command (e.g., WRITE_BYTE), the target discards the incoming command due to the wait or stop being detected. Therefore, the command is not acknowledged by the target, which means that the ACK pulse will not be issued in this case. After a certain time the host (not aware of stop or wait) should decide to abort any possible pending ACK pulse in order to be sure a new command can be issued. Therefore, the protocol provides a mechanism in which a command, and its corresponding ACK, can be aborted.
NOTE
The ACK pulse does not provide a time out. This means for the GO_UNTIL command that it can not be distinguished if a stop or wait has been executed (command discarded and ACK not issued) or if the “UNTIL” condition (BDM active) is just not reached yet. Hence in any case where the ACK pulse of a command is not issued the possible pending command should be aborted before issuing a new command. See the handshake abort procedure described in Section 5.4.8, “Hardware Handshake Abort Procedure”.

5.4.8 Hardware Handshake Abort Procedure

The abort procedure is based on the SYNC command. In order to abort a command, which had not issued the corresponding ACK pulse, the host controller should generate a low pulse in the BKGD pin by driving it low for at least 128 serial clock cycles and then driving it high for one serial clock cycle, providing a speedup pulse. By detecting this long low pulse in the BKGD pin, the target executes the SYNC protocol, see Section 5.4.9, “SYNC — Request Timed Reference Pulse”, and assumes that the pending command and therefore the related ACK pulse, are being aborted. Therefore, after the SYNC protocol has been completed the host is free to issue new BDM commands. For BDM firmware READ or WRITE commands it can not be guaranteed that the pending command is aborted when issuing a SYNC before the corresponding ACK pulse. There is a short latency time from the time the READ or WRITE access begins until it is finished and the corresponding ACK pulse is issued. The latency time depends on the firmware READ or WRITE command that is issued and on the selected bus clock rate. When the SYNC command starts during this latency time the READ or WRITE command will not be aborted, but the corresponding ACK pulse will be aborted. A pending GO, TRACE1 or GO_UNTIL command can not be aborted. Only the corresponding ACK pulse can be aborted by the SYNC command.

Although it is not recommended, the host could abort a pending BDM command by issuing a low pulse in the BKGD pin shorter than 128 serial clock cycles, which will not be interpreted as the SYNC command. The ACK is actually aborted when a negative edge is perceived by the target in the BKGD pin. The short abort pulse should have at least 4 clock cycles keeping the BKGD pin low, in order to allow the negative edge to be detected by the target. In this case, the target will not execute the SYNC protocol but the pending command will be aborted along with the ACK pulse. The potential problem with this abort procedure is when there is a conflict between the ACK pulse and the short abort pulse. In this case, the target may not perceive the abort pulse. The worst case is when the pending command is a read command (i.e., READ_BYTE). If the abort pulse is not perceived by the target the host will attempt to send a new command after the abort pulse was issued, while the target expects the host to retrieve the accessed memory byte. In this case, host and target will run out of synchronism. However, if the command to be aborted is not a read command the short abort pulse could be used. After a command is aborted the target assumes the next negative edge, after the abort pulse, is the first bit of a new BDM command.

NOTE
The details about the short abort pulse are being provided only as a reference for the reader to better understand the BDM internal behavior. It is not recommended that this procedure be used in a real application.
Since the host knows the target serial clock frequency, the SYNC command (used to abort a command) does not need to consider the lower possible target frequency. In this case, the host could issue a SYNC very close to the 128 serial clock cycles length. Providing a small overhead on the pulse length in order to assure the SYNC pulse will not be misinterpreted by the target. See Section 5.4.9, “SYNC — Request Timed Reference Pulse”.

Figure 5-12 shows a SYNC command being issued after a READ_BYTE, which aborts the READ_BYTE command. Note that, after the command is aborted a new command could be issued by the host computer.

**NOTE**

Figure 5-12 does not represent the signals in a true timing scale

Figure 5-13 shows a conflict between the ACK pulse and the SYNC request pulse. This conflict could occur if a POD device is connected to the target BKGD pin and the target is already in debug active mode. Consider that the target CPU is executing a pending BDM command at the exact moment the POD is being connected to the BKGD pin. In this case, an ACK pulse is issued along with the SYNC command. In this case, there is an electrical conflict between the ACK speedup pulse and the SYNC pulse. Since this is not a probable situation, the protocol does not prevent this conflict from happening.
NOTE

This information is being provided so that the MCU integrator will be aware that such a conflict could occur.

The hardware handshake protocol is enabled by the ACK_ENABLE and disabled by the ACK_DISABLE BDM commands. This provides backwards compatibility with the existing POD devices which are not able to execute the hardware handshake protocol. It also allows for new POD devices, that support the hardware handshake protocol, to freely communicate with the target device. If desired, without the need for waiting for the ACK pulse.

The commands are described as follows:

- **ACK_ENABLE** — enables the hardware handshake protocol. The target will issue the ACK pulse when a CPU command is executed by the CPU. The ACK_ENABLE command itself also has the ACK pulse as a response.
- **ACK_DISABLE** — disables the ACK pulse protocol. In this case, the host needs to use the worst case delay time at the appropriate places in the protocol.

The default state of the BDM after reset is hardware handshake protocol disabled.

All the read commands will ACK (if enabled) when the data bus cycle has completed and the data is then ready for reading out by the BKGD serial pin. All the write commands will ACK (if enabled) after the data has been received by the BDM through the BKGD serial pin and when the data bus cycle is complete. See Section 5.4.3, “BDM Hardware Commands” and Section 5.4.4, “Standard BDM Firmware Commands” for more information on the BDM commands.

The ACK_ENABLE sends an ACK pulse when the command has been completed. This feature could be used by the host to evaluate if the target supports the hardware handshake protocol. If an ACK pulse is issued in response to this command, the host knows that the target supports the hardware handshake protocol. If the target does not support the hardware handshake protocol the ACK pulse is not issued. In this case, the ACK_ENABLE command is ignored by the target since it is not recognized as a valid command.

The BACKGROUND command will issue an ACK pulse when the CPU changes from normal to background mode. The ACK pulse related to this command could be aborted using the SYNC command.

The GO command will issue an ACK pulse when the CPU exits from background mode. The ACK pulse related to this command could be aborted using the SYNC command.

The GO_UNTIL command is equivalent to a GO command with exception that the ACK pulse, in this case, is issued when the CPU enters into background mode. This command is an alternative to the GO command and should be used when the host wants to trace if a breakpoint match occurs and causes the CPU to enter active background mode. Note that the ACK is issued whenever the CPU enters BDM, which could be caused by a breakpoint match or by a BGND instruction being executed. The ACK pulse related to this command could be aborted using the SYNC command.

The TRACE1 command has the related ACK pulse issued when the CPU enters background active mode after one instruction of the application program is executed. The ACK pulse related to this command could be aborted using the SYNC command.
5.4.9  **SYNC — Request Timed Reference Pulse**

The SYNC command is unlike other BDM commands because the host does not necessarily know the correct communication speed to use for BDM communications until after it has analyzed the response to the SYNC command. To issue a SYNC command, the host should perform the following steps:

1. Drive the BKGD pin low for at least 128 cycles at the lowest possible BDM serial communication frequency. (The lowest serial communication frequency is determined by the settings for the VCO clock (CPMUSYNR). The BDM clock frequency is always VCO clock frequency divided by 8.)
2. Drive BKGD high for a brief speedup pulse to get a fast rise time (this speedup pulse is typically one cycle of the host clock.)
3. Remove all drive to the BKGD pin so it reverts to high impedance.
4. Listen to the BKGD pin for the sync response pulse.

Upon detecting the SYNC request from the host, the target performs the following steps:

1. Discards any incomplete command received or bit retrieved.
2. Waits for BKGD to return to a logic one.
3. Delays 16 cycles to allow the host to stop driving the high speedup pulse.
4. Drives BKGD low for 128 cycles at the current BDM serial communication frequency.
5. Drives a one-cycle high speedup pulse to force a fast rise time on BKGD.
6. Removes all drive to the BKGD pin so it reverts to high impedance.

The host measures the low time of this 128 cycle SYNC response pulse and determines the correct speed for subsequent BDM communications. Typically, the host can determine the correct communication speed within a few percent of the actual target speed and the communication protocol can easily tolerate speed errors of several percent.

As soon as the SYNC request is detected by the target, any partially received command or bit retrieved is discarded. This is referred to as a soft-reset, equivalent to a time-out in the serial communication. After the SYNC response, the target will consider the next negative edge (issued by the host) as the start of a new BDM command or the start of new SYNC request.

Another use of the SYNC command pulse is to abort a pending ACK pulse. The behavior is exactly the same as in a regular SYNC command. Note that one of the possible causes for a command to not be acknowledged by the target is a host-target synchronization problem. In this case, the command may not have been understood by the target and so an ACK response pulse will not be issued.

5.4.10  **Instruction Tracing**

When a TRACE1 command is issued to the BDM in active BDM, the CPU exits the standard BDM firmware and executes a single instruction in the user code. Once this has occurred, the CPU is forced to return to the standard BDM firmware and the BDM is active and ready to receive a new command. If the TRACE1 command is issued again, the next user instruction will be executed. This facilitates stepping or tracing through the user code one instruction at a time.
If an interrupt is pending when a TRACE1 command is issued, the interrupt stacking operation occurs but no user instruction is executed. Once back in standard BDM firmware execution, the program counter points to the first instruction in the interrupt service routine.

Be aware when tracing through the user code that the execution of the user code is done step by step but all peripherals are free running. Hence possible timing relations between CPU code execution and occurrence of events of other peripherals no longer exist.

Do not trace the CPU instruction BGND used for soft breakpoints. Tracing over the BGND instruction will result in a return address pointing to BDM firmware address space.

When tracing through user code which contains stop or wait instructions the following will happen when the stop or wait instruction is traced:

The CPU enters stop or wait mode and the TRACE1 command can not be finished before leaving the low power mode. This is the case because BDM active mode can not be entered after CPU executed the stop instruction. However all BDM hardware commands except the BACKGROUND command are operational after tracing a stop or wait instruction and still being in stop or wait mode. If system stop mode is entered (all bus masters are in stop mode) no BDM command is operational.

As soon as stop or wait mode is exited the CPU enters BDM active mode and the saved PC value points to the entry of the corresponding interrupt service routine.

In case the handshake feature is enabled the corresponding ACK pulse of the TRACE1 command will be discarded when tracing a stop or wait instruction. Hence there is no ACK pulse when BDM active mode is entered as part of the TRACE1 command after CPU exited from stop or wait mode. All valid commands sent during CPU being in stop or wait mode or after CPU exited from stop or wait mode will have an ACK pulse. The handshake feature becomes disabled only when system stop mode has been reached. Hence after a system stop mode the handshake feature must be enabled again by sending the ACK_ENABLE command.

5.4.11 Serial Communication Time Out

The host initiates a host-to-target serial transmission by generating a falling edge on the BKGD pin. If BKGD is kept low for more than 128 target clock cycles, the target understands that a SYNC command was issued. In this case, the target will keep waiting for a rising edge on BKGD in order to answer the SYNC request pulse. If the rising edge is not detected, the target will keep waiting forever without any time-out limit.

Consider now the case where the host returns BKGD to logic one before 128 cycles. This is interpreted as a valid bit transmission, and not as a SYNC request. The target will keep waiting for another falling edge marking the start of a new bit. If, however, a new falling edge is not detected by the target within 512 clock cycles since the last falling edge, a time-out occurs and the current command is discarded without affecting memory or the operating mode of the MCU. This is referred to as a soft-reset.

If a read command is issued but the data is not retrieved within 512 serial clock cycles, a soft-reset will occur causing the command to be disregarded. The data is not available for retrieval after the time-out has occurred. This is the expected behavior if the handshake protocol is not enabled. In order to allow the data to be retrieved even with a large clock frequency mismatch (between BDM and CPU) when the hardware
handshake protocol is enabled, the time out between a read command and the data retrieval is disabled. Therefore, the host could wait for more than 512 serial clock cycles and still be able to retrieve the data from an issued read command. However, once the handshake pulse (ACK pulse) is issued, the time-out feature is re-activated, meaning that the target will time out after 512 clock cycles. Therefore, the host needs to retrieve the data within a 512 serial clock cycles time frame after the ACK pulse had been issued. After that period, the read command is discarded and the data is no longer available for retrieval. Any negative edge in the BKGD pin after the time-out period is considered to be a new command or a SYNC request.

Note that whenever a partially issued command, or partially retrieved data, has occurred the time out in the serial communication is active. This means that if a time frame higher than 512 serial clock cycles is observed between two consecutive negative edges and the command being issued or data being retrieved is not complete, a soft-reset will occur causing the partially received command or data retrieved to be disregarded. The next negative edge in the BKGD pin, after a soft-reset has occurred, is considered by the target as the start of a new BDM command, or the start of a SYNC request pulse.
Chapter 6
S12S Debug Module (S12SDBGV2)

6.1 Introduction

The S12SDBG module provides an on-chip trace buffer with flexible triggering capability to allow non-intrusive debug of application software. The S12SDBG module is optimized for S12SCPU debugging.

Typically the S12SDBG module is used in conjunction with the S12SBDM module, whereby the user configures the S12SDBG module for a debugging session over the BDM interface. Once configured the S12SDBG module is armed and the device leaves BDM returning control to the user program, which is then monitored by the S12SDBG module. Alternatively the S12SDBG module can be configured over a serial interface using SWI routines.

6.1.1 Glossary Of Terms

COF: Change Of Flow. Change in the program flow due to a conditional branch, indexed jump or interrupt.
BDM: Background Debug Mode
S12SBDM: Background Debug Module
DUG: Device User Guide, describing the features of the device into which the DBG is integrated.
WORD: 16 bit data entity
Data Line: 20 bit data entity
CPU: S12SCPU module
DBG: S12SDBG module
POR: Power On Reset
Tag: Tags can be attached to CPU opcodes as they enter the instruction pipe. If the tagged opcode reaches the execution stage a tag hit occurs.
6.1.2 Overview

The comparators monitor the bus activity of the CPU module. A match can initiate a state sequencer transition. On a transition to the Final State, bus tracing is triggered and/or a breakpoint can be generated. Independent of comparator matches a transition to Final State with associated tracing and breakpoint can be triggered immediately by writing to the TRIG control bit.

The trace buffer is visible through a 2-byte window in the register address map and can be read out using standard 16-bit word reads. Tracing is disabled when the MCU system is secured.

6.1.3 Features

• Three comparators (A, B and C)
  — Comparators A compares the full address bus and full 16-bit data bus
  — Comparator A features a data bus mask register
  — Comparators B and C compare the full address bus only
  — Each comparator features selection of read or write access cycles
  — Comparator B allows selection of byte or word access cycles
  — Comparator matches can initiate state sequencer transitions

• Three comparator modes
  — Simple address/data comparator match mode
  — Inside address range mode, \( \text{Addmin} \leq \text{Address} \leq \text{Addmax} \)
  — Outside address range match mode, \( \text{Address} < \text{Addmin} \text{ or Address} > \text{Addmax} \)

• Two types of matches
  — Tagged — This matches just before a specific instruction begins execution
  — Force — This is valid on the first instruction boundary after a match occurs

• Two types of breakpoints
  — CPU breakpoint entering BDM on breakpoint (BDM)
  — CPU breakpoint executing SWI on breakpoint (SWI)

• Trigger mode independent of comparators
  — TRIG Immediate software trigger

• Four trace modes
  — Normal: change of flow (COF) PC information is stored (see 6.4.5.2.1) for change of flow definition.
  — Loop1: same as Normal but inhibits consecutive duplicate source address entries
  — Detail: address and data for all cycles except free cycles and opcode fetches are stored
  — Compressed Pure PC: all program counter addresses are stored

• 4-stage state sequencer for trace buffer control
  — Tracing session trigger linked to Final State of state sequencer
  — Begin and End alignment of tracing to trigger
6.1.4 **Modes of Operation**

The DBG module can be used in all MCU functional modes.

During BDM hardware accesses and whilst the BDM module is active, CPU monitoring is disabled. When the CPU enters active BDM Mode through a BACKGROUND command, the DBG module, if already armed, remains armed.

The DBG module tracing is disabled if the MCU is secure, however, breakpoints can still be generated.

Figure 6-2. Quick Reference to DBG Registers

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor
This section consists of the DBG control and trace buffer register descriptions in address order. Each comparator has a bank of registers that are visible through an 8-byte window between 0x0028 and 0x002F in the DBG module register address map. When ARM is set in DBGC1, the only bits in the DBG module registers that can be written are ARM, TRIG, and COMRV[1:0].

### 6.3.2.1 Debug Control Register 1 (DBGC1)

Address: 0x0020

![Figure 6-3. Debug Control Register (DBGC1)](image)

Read: Anytime

Write: Bits 7, 1, 0 anytime

- Bit 6 can be written anytime but always reads back as 0.
- Bits 4:3 anytime DBG is not armed.

**NOTE**

When disarming the DBG by clearing ARM with software, the contents of bits[4:3] are not affected by the write, since up until the write operation, ARM = 1 preventing these bits from being written. These bits must be cleared using a second write if required.
Table 6-3. DBGC1 Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 ARM | **Arm Bit** — The ARM bit controls whether the DBG module is armed. This bit can be set and cleared by user software and is automatically cleared on completion of a debug session, or if a breakpoint is generated with tracing not enabled. On setting this bit the state sequencer enters State1.  
0 Debug arm disabled  
1 Debug arm enabled |
| 6 TRIG | Immediate Trigger Request Bit — This bit when written to 1 requests an immediate trigger independent of state sequencer status. When tracing is complete, a forced breakpoint may be generated depending upon DBGBRK and BDM bit settings. This bit always reads back a 0. Writing a 0 to this bit has no effect. If the DBGTCR_TSOURCE bit is clear no tracing is carried out. If tracing has already commenced using BEGIN trigger alignment, it continues until the end of the tracing session as defined by the TALIGN bit, thus TRIG has no effect. In secure mode tracing is disabled and writing to this bit cannot initiate a tracing session.  
The session is ended by setting TRIG and ARM simultaneously.  
0 Do not trigger until the state sequencer enters the Final State.  
1 Trigger immediately |
| 4 BDM | Background Debug Mode Enable — This bit determines if a breakpoint causes the system to enter Background Debug Mode (BDM) or initiate a Software Interrupt (SWI). If this bit is set but the BDM is not enabled by the ENBDM bit in the BDM module, then breakpoints default to SWI.  
0 Breakpoint to Software Interrupt if BDM inactive. Otherwise no breakpoint.  
1 Breakpoint to BDM, if BDM enabled. Otherwise breakpoint to SWI |
| 3 DBG | S12SDBG Breakpoint Enable Bit — The DBGBRK bit controls whether the debugger will request a breakpoint on reaching the state sequencer Final State. If tracing is enabled, the breakpoint is generated on completion of the tracing session. If tracing is not enabled, the breakpoint is generated immediately.  
0 No Breakpoint generated  
1 Breakpoint generated |
| 1–0 COMRV | Comparator Register Visibility Bits — These bits determine which bank of comparator register is visible in the 8-byte window of the S12SDBG module address map, located between 0x0028 to 0x002F. Furthermore, these bits determine which register is visible at the address 0x0027. See Table 6-4. |

<td><strong>Trace Buffer Full</strong> — The TBF bit indicates that the trace buffer has stored 64 or more lines of data since it was last armed. If this bit is set, all 64 lines will be valid data, regardless of the value of DBGCNT bits. The TBF bit is cleared when ARM in DBGC1 is written to a one. The TBF is cleared by the power on reset initialization. Other system generated resets have no affect on this bit. This bit is also visible at DBGSR[7].</td>
</tr>
</tbody>
</table>

| 5–0 | **CNT[5:0]**
|     | **Count Value** — The CNT bits indicate the number of valid data 20-bit data lines stored in the Trace Buffer. Table 6-13 shows the correlation between the CNT bits and the number of valid data lines in the Trace Buffer. When the CNT rolls over to zero, the TBF bit in DBGSR is set and incrementing of CNT will continue in end-trigger mode. The DBGCNT register is cleared when ARM in DBGC1 is written to a one. The DBGCNT register is cleared by power-on-reset initialization but is not cleared by other system resets. Thus should a reset occur during a debug session, the DBGCNT register still indicates after the reset, the number of valid trace buffer entries stored before the reset occurred. The DBGCNT register is not decremented when reading from the trace buffer. |

6.3.2.7 Debug State Control Registers

There is a dedicated control register for each of the state sequencer states 1 to 3 that determines if transitions from that state are allowed, depending upon comparator matches or tag hits, and defines the next state for the state sequencer following a match. The three debug state control registers are located at the same address in the register address map (0x0027). Each register can be accessed using the COMRV bits in DBGC1 to blend in the required register. The COMRV = 11 value blends in the match flag register (DBGMFR).

<td>MC0</td>
</tr>
</tbody>
</table>

**Reset:** 00000000

#### Figure 6-12. Debug Match Flag Register (DBGMFR)

**Read:** If COMRV[1:0] = 11

**Write:** Never

DBGMFR is visible at 0x0027 only with COMRV[1:0] = 11. It features 3 flag bits each mapped directly to a channel. Should a match occur on the channel during the debug session, then the corresponding flag is set and remains set until the next time the module is armed by writing to the ARM bit. Thus the contents are retained after a debug session for evaluation purposes. These flags cannot be cleared by software, they are cleared only when arming the module. A set flag does not inhibit the setting of other flags. Once a flag is set, further comparator matches on the same channel in the same session have no effect on that flag.

### 6.3.2.8 Comparator Register Descriptions

Each comparator has a bank of registers that are visible through an 8-byte window in the DBG module register address map. Comparator A consists of 8 register bytes (3 address bus compare registers, two data bus compare registers, two data bus mask registers and a control register). Comparator B consists of four register bytes (three address bus compare registers and a control register). Comparator C consists of four register bytes (three address bus compare registers and a control register).

Each set of comparator registers can be accessed using the COMRV bits in the DBGCl register. Unimplemented registers (e.g. Comparator B data bus and data bus masking) read as zero and cannot be written. The control register for comparator B differs from those of comparators A and C.

#### Table 6-21. Comparator Register Layout

6.4 Functional Description

This section provides a complete functional description of the DBG module. If the part is in secure mode, the DBG module can generate breakpoints but tracing is not possible.

6.4.1 S12SDBG Operation

Arming the DBG module by setting ARM in DBGC1 allows triggering the state sequencer, storing of data in the trace buffer and generation of breakpoints to the CPU. The DBG module is made up of four main blocks, the comparators, control logic, the state sequencer, and the trace buffer.

The comparators monitor the bus activity of the CPU. All comparators can be configured to monitor address bus activity. Comparator A can also be configured to monitor databus activity and mask out individual data bus bits during a compare. Comparators can be configured to use R/W and word/byte access qualification in the comparison. A match with a comparator register value can initiate a state sequencer transition to another state (see Figure 6-24). Either forced or tagged matches are possible. Using
a forced match, a state sequencer transition can occur immediately on a successful match of system busses and comparator registers. Whilst tagging, at a comparator match, the instruction opcode is tagged and only if the instruction reaches the execution stage of the instruction queue can a state sequencer transition occur. In the case of a transition to Final State, bus tracing is triggered and/or a breakpoint can be generated.

A state sequencer transition to final state (with associated breakpoint, if enabled) can be initiated by writing to the TRIG bit in the DBGC1 control register.

The trace buffer is visible through a 2-byte window in the register address map and must be read out using standard 16-bit word reads.

6.4.2 Comparator Modes

The DBG contains three comparators, A, B and C. Each comparator compares the system address bus with the address stored in DBGXAH, DBGXAM, and DBGXAL. Furthermore, comparator A also compares the data buses to the data stored in DBGADH, DBGADL and allows masking of individual data bus bits.

All comparators are disabled in BDM and during BDM accesses.

The comparator match control logic (see Figure 6-23) configures comparators to monitor the buses for an exact address or an address range, whereby either an access inside or outside the specified range generates a match condition. The comparator configuration is controlled by the control register contents and the range control by the DBGC2 contents.

A match can initiate a transition to another state sequencer state (see 6.4.4”). The comparator control register also allows the type of access to be included in the comparison through the use of the RWE, RW, SZE, and SZ bits. The RWE bit controls whether read or write comparison is enabled for the associated comparator and the RW bit selects either a read or write access for a valid match. Similarly the SZE and
SZ bits allow the size of access (word or byte) to be considered in the compare. Only comparators A and B feature SZE and SZ.

The TAG bit in each comparator control register is used to determine the match condition. By setting TAG, the comparator qualifies a match with the output of opcode tracking logic and a state sequencer transition occurs when the tagged instruction reaches the CPU execution stage. Whilst tagging the RW, RWE, SZE, and SZ bits and the comparator data registers are ignored; the comparator address register must be loaded with the exact opcode address.

If the TAG bit is clear (forced type match) a comparator match is generated when the selected address appears on the system address bus. If the selected address is an opcode address, the match is generated when the opcode is fetched from the memory, which precedes the instruction execution by an indefinite number of cycles due to instruction pipelining. For a comparator match of an opcode at an odd address when TAG = 0, the corresponding even address must be contained in the comparator register. Thus for an opcode at odd address (n), the comparator register must contain address (n–1).

Once a successful comparator match has occurred, the condition that caused the original match is not verified again on subsequent matches. Thus if a particular data value is verified at a given address, this address may not still contain that data value when a subsequent match occurs.

Match[0, 1, 2] map directly to Comparators [A, B, C] respectively, except in range modes (see 6.3.2.4). Comparator channel priority rules are described in the priority section (6.4.3.4).

6.4.2.1 Single Address Comparator Match
With range comparisons disabled, the match condition is an exact equivalence of address bus with the value stored in the comparator address registers. Further qualification of the type of access (R/W, word/byte) and databus contents is possible, depending on comparator channel.

6.4.2.1.1 Comparator C
Comparator C offers only address and direction (R/W) comparison. The exact address is compared, thus with the comparator address register loaded with address (n) a word access of address (n–1) also accesses (n) but does not cause a match.

<table>
<thead>
<tr>
<th>Condition For Valid Match</th>
<th>Comp C Address</th>

</tr>
<tr>
<td>Read accesses of ADDR[n]</td>
<td>ADDR[n]</td>
<td>1</td>
<td>1</td>
<td>LDAA #$BYTE ADDR[n]</td>
</tr>
</tbody>
</table>

¹: A word access of ADDR[n–1] also accesses ADDR[n] but does not generate a match.

The comparator address register must contain the exact address from the code.

6.4.2.1.2 Comparator B
Comparator B offers address, direction (R/W) and access size (word/byte) comparison. If the SZE bit is set the access size (word or byte) is compared with the SZ bit value such that only the specified size of
access causes a match. Thus if configured for a byte access of a particular address, a word access covering
the same address does not lead to match.

Assuming the access direction is not qualified (RWE=0), for simplicity, the size access considerations are
shown in Table 6-33.

### Table 6-33. Comparator B Access Size Considerations

<table>
<thead>
<tr>
<th>Condition For Valid Match</th>
<th>Comp B Address</th>
<th>RWE</th>
<th>SZ</th>
<th>Examples</th>
</tr>
</thead>
<tbody>

<td>ADDR[n]</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Byte accesses of ADDR[n] only</td>
<td>ADDR[n]</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

1: A word access of ADDR[n-1] also accesses ADDR[n] but does not generate a match.

The comparator address register must contain the exact address from the code.

Access direction can also be used to qualify a match for Comparator B in the same way as described for
Comparator C in Table 6-32.

### 6.4.2.1.3 Comparator A

Comparator A offers address, direction (R/W), access size (word/byte) and data bus comparison.

Table 6-34 lists access considerations with data bus comparison. On word accesses the data byte of the
lower address is mapped to DBGADH. Access direction can also be used to qualify a match for
Comparator A in the same way as described for Comparator C in Table 6-32.

</tbody>
</table>
6.4.2.1.4 Comparator A Data Bus Comparison NDB Dependency

Comparator A features an NDB control bit, which allows data bus comparators to be configured to either trigger on equivalence or trigger on difference. This allows monitoring of a difference in the contents of an address location from an expected value.

When matching on an equivalence (NDB=0), each individual data bus bit position can be masked out by clearing the corresponding mask bit (DBGADHM/DBGADLM) so that it is ignored in the comparison. A match occurs when all data bus bits with corresponding mask bits set are equivalent. If all mask register bits are clear, then a match is based on the address bus only, the data bus is ignored.

When matching on a difference, mask bits can be cleared to ignore bit positions. A match occurs when any data bus bit with corresponding mask bit set is different. Clearing all mask bits, causes all bits to be ignored and prevents a match because no difference can be detected. In this case address bus equivalence does not cause a match.

</tr>
</tbody>
</table>

6.4.2.2 Range Comparisons

Using the AB comparator pair for a range comparison, the data bus can also be used for qualification by using the comparator A data registers. Furthermore the DBGACTL RW and RWE bits can be used to qualify the range comparison on either a read or a write access. The corresponding DBGBCTL bits are ignored. The SZE and SZ control bits are ignored in range mode. The comparator A TAG bit is used to tag range comparisons. The comparator B TAG bit is ignored in range modes. In order for a range comparison using comparators A and B, both COMPEA and COMPEB must be set; to disable range comparisons both must be cleared. The comparator A BRK bit is used to for the AB range, the comparator B BRK bit is ignored in range mode.

When configured for range comparisons and tagging, the ranges are accurate only to word boundaries.

6.4.2.2.1 Inside Range (CompA_Addr ≤ address ≤ CompB_Addr)

In the Inside Range comparator mode, comparator pair A and B can be configured for range comparisons. This configuration depends upon the control register (DBGC2). The match condition requires that a valid match for both comparators happens on the same bus cycle. A match condition on only one comparator is not valid. An aligned word access which straddles the range boundary is valid only if the aligned address is inside the range.
6.4.2.2.2 Outside Range (address < CompA_Addr or address > CompB_Addr)

In the Outside Range comparator mode, comparator pair A and B can be configured for range comparisons. A single match condition on either of the comparators is recognized as valid. An aligned word access which straddles the range boundary is valid only if the aligned address is outside the range.

Outside range mode in combination with tagging can be used to detect if the opcode fetches are from an unexpected range. In forced match mode the outside range match would typically be activated at any interrupt vector fetch or register access. This can be avoided by setting the upper range limit to $3FFFF or lower range limit to $00000 respectively.

6.4.3 Match Modes (Forced or Tagged)

Match modes are used as qualifiers for a state sequencer change of state. The Comparator control register TAG bits select the match mode. The modes are described in the following sections.

6.4.3.1 Forced Match

When configured for forced matching, a comparator channel match can immediately initiate a transition to the next state sequencer state whereby the corresponding flags in DBGSR are set. The state control register for the current state determines the next state. Forced matches are typically generated 2-3 bus cycles after the final matching address bus cycle, independent of comparator RWE/RW settings. Furthermore since opcode fetches occur several cycles before the opcode execution a forced match of an opcode address typically precedes a tagged match at the same address.

6.4.3.2 Tagged Match

If a CPU taghit occurs a transition to another state sequencer state is initiated and the corresponding DBGSR flags are set. For a comparator related taghit to occur, the DBG must first attach tags to instructions as they are fetched from memory. When the tagged instruction reaches the execution stage of the instruction queue a taghit is generated by the CPU. This can initiate a state sequencer transition.

6.4.3.3 Immediate Trigger

Independent of comparator matches it is possible to initiate a tracing session and/or breakpoint by writing to the TRIG bit in DBGC1. If configured for begin aligned tracing, this triggers the state sequencer into the Final State, if configured for end alignment, setting the TRIG bit disarms the module, ending the session and issues a forced breakpoint request to the CPU.

It is possible to set both TRIG and ARM simultaneously to generate an immediate trigger, independent of the current state of ARM.

6.4.3.4 Channel Priorities

In case of simultaneous matches the priority is resolved according to Table 6-36. The lower priority is suppressed. It is thus possible to miss a lower priority match if it occurs simultaneously with a higher priority. The priorities described in Table 6-36 dictate that in the case of simultaneous matches, the match pointing to final state has highest priority followed by the lower channel number (0,1,2).
6.4.4 State Sequence Control

The state sequencer allows a defined sequence of events to provide a trigger point for tracing of data in the trace buffer. Once the DBG module has been armed by setting the ARM bit in the DBGC1 register, then state1 of the state sequencer is entered. Further transitions between the states are then controlled by the state control registers and channel matches. From Final State the only permitted transition is back to the disarmed state0. Transition between any of the states 1 to 3 is not restricted. Each transition updates the SSF[2:0] flags in DBGSR accordingly to indicate the current state.

Alternatively writing to the TRIG bit in DBGSC1, provides an immediate trigger independent of comparator matches.

Independent of the state sequencer, each comparator channel can be individually configured to generate an immediate breakpoint when a match occurs through the use of the BRK bits in the DBGxCTL registers. Thus it is possible to generate an immediate breakpoint on selected channels, whilst a state sequencer transition can be initiated by a match on other channels. If a debug session is ended by a match on a channel the state sequencer transitions through Final State for a clock cycle to state0. This is independent of tracing and breakpoint activity, thus with tracing and breakpoints disabled, the state sequencer enters state0 and the debug module is disarmed.

6.4.4.1 Final State

On entering Final State a trigger may be issued to the trace buffer according to the trace alignment control as defined by the TALIGN bit (see 6.3.2.3”). If the TSOURCE bit in DBGTCR is clear then the trace buffer

Figure 6-24. State Sequencer Diagram

The state sequencer diagram shows the transitions between states 0 to 3, with ARM and Session Complete states transitions defined. The diagram illustrates how state transitions are controlled by the state control registers and channel matches.
is disabled and the transition to Final State can only generate a breakpoint request. In this case or upon completion of a tracing session when tracing is enabled, the ARM bit in the DBGC1 register is cleared, returning the module to the disarmed state0. If tracing is enabled a breakpoint request can occur at the end of the tracing session. If neither tracing nor breakpoints are enabled then when the final state is reached it returns automatically to state0 and the debug module is disarmed.

### 6.4.5 Trace Buffer Operation

The trace buffer is a 64 lines deep by 20-bits wide RAM array. The DBG module stores trace information in the RAM array in a circular buffer format. The system accesses the RAM array through a register window (DBGTBH:DBGTBL) using 16-bit wide word accesses. After each complete 20-bit trace buffer line is read, an internal pointer into the RAM increments so that the next read receives fresh information. Data is stored in the format shown in Table 6-37 and Table 6-40. After each store the counter register DBGCNT is incremented. Tracing of CPU activity is disabled when the BDM is active. Reading the trace buffer whilst the DBG is armed returns invalid data and the trace buffer pointer is not incremented.

#### 6.4.5.1 Trace Trigger Alignment

Using the TALIGN bit (see 6.3.2.3) it is possible to align the trigger with the end or the beginning of a tracing session.

If end alignment is selected, tracing begins when the ARM bit in DBGC1 is set and State1 is entered; the transition to Final State signals the end of the tracing session. Tracing with Begin-Trigger starts at the opcode of the trigger. Using end alignment or when the tracing is initiated by writing to the TRIG bit whilst configured for begin alignment, tracing starts in the second cycle after the DBGC1 write cycle.

##### 6.4.5.1.1 Storing with Begin Trigger Alignment

Storing with begin alignment, data is not stored in the Trace Buffer until the Final State is entered. Once the trigger condition is met the DBG module remains armed until 64 lines are stored in the Trace Buffer. If the trigger is at the address of the change-of-flow instruction the change of flow associated with the trigger is stored in the Trace Buffer. Using begin alignment together with tagging, if the tagged instruction is about to be executed then the trace is started. Upon completion of the tracing session the breakpoint is generated, thus the breakpoint does not occur at the tagged instruction boundary.

##### 6.4.5.1.2 Storing with End Trigger Alignment

Storing with end alignment, data is stored in the Trace Buffer until the Final State is entered, at which point the DBG module becomes disarmed and no more data is stored. If the trigger is at the address of a change of flow instruction, the trigger event is not stored in the Trace Buffer. If all trace buffer lines have been used before a trigger event occurs then the trace continues at the first line, overwriting the oldest entries.

#### 6.4.5.2 Trace Modes

Four trace modes are available. The mode is selected using the TRCMOD bits in the DBGTCR register. Tracing is enabled using the TSOURCE bit in the DBGTCR register. The modes are described in the following subsections.
6.4.5.2.1 Normal Mode

In Normal Mode, change of flow (COF) program counter (PC) addresses are stored.

COF addresses are defined as follows:

- Source address of taken conditional branches (long, short, bit-conditional, and loop primitives)
- Destination address of indexed JMP, JSR, and CALL instruction
- Destination address of RTI, RTS, and RTC instructions
- Vector address of interrupts, except for BDM vectors

LBRA, BRA, BSR, BGND as well as non-indexed JMP, JSR, and CALL instructions are not classified as change of flow and are not stored in the trace buffer.

Stored information includes the full 18-bit address bus and information bits, which contains a source/destination bit to indicate whether the stored address was a source address or destination address.

**NOTE**

When a COF instruction with destination address is executed, the destination address is stored to the trace buffer on instruction completion, indicating the COF has taken place. If an interrupt occurs simultaneously then the next instruction carried out is actually from the interrupt service routine. The instruction at the destination address of the original program flow gets executed after the interrupt service routine.

In the following example an IRQ interrupt occurs during execution of the indexed JMP at address MARK1. The BRN at the destination (SUB_1) is not executed until after the IRQ service routine but the destination address is entered into the trace buffer to indicate that the indexed JMP COF has taken place.

```assembly
LDX #SUB_1
MARK1 JMP 0,X ; IRQ interrupt occurs during execution of this
MARK2 NOP ;
SUB_1 BRN * ; JMP Destination address TRACE BUFFER ENTRY 1
SUB_1 NOP ; RTI Destination address TRACE BUFFER ENTRY 3
ADDR1 DBNE A, PART5 ; Source address TRACE BUFFER ENTRY 4
IRQ_ISR LDAB #$F0 ; IRQ Vector $FF2 = TRACE BUFFER ENTRY 2
STAB VAR_C1
RTI

The execution flow taking into account the IRQ is as follows
```

```assembly
LDX #SUB_1
MARK1 JMP 0,X ;
IRQ_ISR LDAB #$F0 ;
STAB VAR_C1
RTI

SUB_1 BRN * ;
NOP ;
ADDR1 DBNE A, PART5 ;
```
6.4.5.2.2 Loop1 Mode

Loop1 Mode, similarly to Normal Mode also stores only COF address information to the trace buffer, it however allows the filtering out of redundant information.

The intent of Loop1 Mode is to prevent the Trace Buffer from being filled entirely with duplicate information from a looping construct such as delays using the DBNE instruction or polling loops using BRSET/BRCLR instructions. Immediately after address information is placed in the Trace Buffer, the DBG module writes this value into a background register. This prevents consecutive duplicate address entries in the Trace Buffer resulting from repeated branches.

Loop1 Mode only inhibits consecutive duplicate source address entries that would typically be stored in most tight looping constructs. It does not inhibit repeated entries of destination addresses or vector addresses, since repeated entries of these would most likely indicate a bug in the user’s code that the DBG module is designed to help find.

6.4.5.2.3 Detail Mode

In Detail Mode, address and data for all memory and register accesses is stored in the trace buffer. This mode is intended to supply additional information on indexed, indirect addressing modes where storing only the destination address would not provide all information required for a user to determine where the code is in error. This mode also features information bit storage to the trace buffer, for each address byte storage. The information bits indicate the size of access (word or byte) and the type of access (read or write).

When tracing in Detail Mode, all cycles are traced except those when the CPU is either in a free or opcode fetch cycle.

6.4.5.2.4 Compressed Pure PC Mode

In Compressed Pure PC Mode, the PC addresses of all executed opcodes, including illegal opcodes are stored. A compressed storage format is used to increase the effective depth of the trace buffer. This is achieved by storing the lower order bits each time and using 2 information bits to indicate if a 64 byte boundary has been crossed, in which case the full PC is stored.

Each Trace Buffer row consists of 2 information bits and 18 PC address bits

NOTE:

When tracing is terminated using forced breakpoints, latency in breakpoint generation means that opcodes following the opcode causing the breakpoint can be stored to the trace buffer. The number of opcodes is dependent on program flow. This can be avoided by using tagged breakpoints.

6.4.5.3 Trace Buffer Organization (Normal, Loop1, Detail modes)

ADRH, ADRM, ADRL denote address high, middle and low byte respectively. The numerical suffix refers to the tracing count. The information format for Loop1 and Normal modes is identical. In Detail mode, the address and data for each entry are stored on consecutive lines, thus the maximum number of entries is 32. In this case DBGCNT bits are incremented twice, once for the address line and once for the data line, on
each trace buffer entry. In Detail mode CINF comprises of R/W and size access information (CRW and CSZ respectively).

Single byte data accesses in Detail Mode are always stored to the low byte of the trace buffer (DATAL) and the high byte is cleared. When tracing word accesses, the byte at the lower address is always stored to trace buffer byte1 and the byte at the higher address is stored to byte0.

</tbody>
</table>

**NOTE**
Configured for end aligned triggering in compressed PurePC mode, then after rollover it is possible that the oldest base address is overwritten. In this case all entries between the pointer and the next base address have lost their base address following rollover. For example in Table 6-40 if one line of rollover has occurred, Line 1, PC1, is overwritten with a new entry. Thus the entries on Lines 2 and 3 have lost their base address. For reconstruction of program flow the first base address following the pointer must be used, in the example, Line 4. The pointer points to the oldest entry, Line 2.

</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Trace Buffer[5:0] contain incremental PC relative to base address zero value</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Trace Buffer[11:0] contain next 2 incremental PCs relative to base address zero value</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Trace Buffer[17:0] contain next 3 incremental PCs relative to base address zero value</td>
</tr>
</tbody>
</table>

Each time that PC[17:6] differs from the previous base PC[17:6], then a new base address is stored. The base address zero value is the lowest address in the 64 address range.

The first line of the trace buffer always gets a base PC address, this applies also on rollover.

6.4.5.5 Reading Data from Trace Buffer

The data stored in the Trace Buffer can be read provided the DBG module is not armed, is configured for tracing (TSource bit is set) and the system not secured. When the ARM bit is written to 1 the trace buffer is locked to prevent reading. The trace buffer can only be unlocked for reading by a single aligned word write to DBGTB when the module is disarmed.

The Trace Buffer can only be read through the DBGTB register using aligned word reads, any byte or misaligned reads return 0 and do not cause the trace buffer pointer to increment to the next trace buffer address. The Trace Buffer data is read out first-in first-out. By reading CNT in DBGCNT the number of valid lines can be determined. DBGCNT does not decrement as data is read.

Whilst reading an internal pointer is used to determine the next line to be read. After a tracing session, the pointer points to the oldest data entry, thus if no rollover has occurred, the pointer points to line0, otherwise it points to the line with the oldest entry. In compressed Pure PC mode on rollover the line with the oldest data entry may also contain newer data entries in fields 0 and 1. Thus if rollover is indicated by the TBF bit, the line status must be decoded using the INF bits in field3 of that line. If both INF bits are clear then the line contains only entries from before the last rollover.

If INF0=1 then field 0 contains post rollover data but fields 1 and 2 contain pre rollover data.
If INF1=1 then fields 0 and 1 contain post rollover data but field 2 contains pre rollover data.

The pointer is initialized by each aligned write to DBGTBH to point to the oldest data again. This enables an interrupted trace buffer read sequence to be easily restarted from the oldest data entry.

The least significant word of line is read out first. This corresponds to the fields 1 and 0 of Table 6-37. The next word read returns field 2 in the least significant bits [3:0] and “0” for bits [15:4].

Reading the Trace Buffer while the DBG module is armed returns invalid data and no shifting of the RAM pointer occurs.

6.4.5.6 Trace Buffer Reset State

The Trace Buffer contents and DBGCNT bits are not initialized by a system reset. Thus should a system reset occur, the trace session information from immediately before the reset occurred can be read out and the number of valid lines in the trace buffer is indicated by DBGCNT. The internal pointer to the current
trace buffer address is initialized by unlocking the trace buffer and points to the oldest valid data even if a 
reset occurred during the tracing session. To read the trace buffer after a reset, TSOURCE must be set, 
otherwise the trace buffer reads as all zeroes. Generally debugging occurrences of system resets is best 
handled using end trigger alignment since the reset may occur before the trace trigger, which in the begin 
trigger alignment case means no information would be stored in the trace buffer.

The Trace Buffer contents and DBGCNT bits are undefined following a POR.

**NOTE**

An external pin RESET that occurs simultaneous to a trace buffer entry can, 
in very seldom cases, lead to either that entry being corrupted or the first 
entry of the session being corrupted. In such cases the other contents of the 
trace buffer still contain valid tracing information. The case occurs when the 
reset assertion coincides with the trace buffer entry clock edge.

### 6.4.6 Tagging

A tag follows program information as it advances through the instruction queue. When a tagged instruction 
reaches the head of the queue a tag hit occurs and can initiate a state sequencer transition.

Each comparator control register features a TAG bit, which controls whether the comparator match causes 
a state sequencer transition immediately or tags the opcode at the matched address. If a comparator is 
enabled for tagged comparisons, the address stored in the comparator match address registers must be an 
opcode address.

Using Begin trigger together with tagging, if the tagged instruction is about to be executed then the 
transition to the next state sequencer state occurs. If the transition is to the Final State, tracing is started. 
Only upon completion of the tracing session can a breakpoint be generated. Using End alignment, when 
the tagged instruction is about to be executed and the next transition is to Final State then a breakpoint is 
generated immediately, before the tagged instruction is carried out.

R/W monitoring, access size (SZ) monitoring and data bus monitoring are not useful if tagging is selected, 
since the tag is attached to the opcode at the matched address and is not dependent on the data bus nor on 
the type of access. Thus these bits are ignored if tagging is selected.

When configured for range comparisons and tagging, the ranges are accurate only to word boundaries. 
Tagging is disabled when the BDM becomes active.

### 6.4.7 Breakpoints

It is possible to generate breakpoints from channel transitions to final state or using software to write to 
the TRIG bit in the DBGCl register.

#### 6.4.7.1 Breakpoints From Comparator Channels

Breakpoints can be generated when the state sequencer transitions to the Final State. If configured for 
tagging, then the breakpoint is generated when the tagged opcode reaches the execution stage of the 
instruction queue.
If a tracing session is selected by the TSOURCE bit, breakpoints are requested when the tracing session has completed, thus if Begin aligned triggering is selected, the breakpoint is requested only on completion of the subsequent trace (see Table 6-42). If no tracing session is selected, breakpoints are requested immediately.

If the BRK bit is set, then the associated breakpoint is generated immediately independent of tracing trigger alignment.

### Table 6-42. Breakpoint Setup For CPU Breakpoints

<td>1</td>
<td>Terminate tracing and generate breakpoint immediately on trigger</td>
</tr>
<tr>
<td>1</td>
<td>x</td>
<td>0</td>
<td>Terminate tracing immediately on trigger</td>
</tr>
</tbody>
</table>

#### 6.4.7.2 Breakpoints Generated Via The TRIG Bit

If a TRIG triggers occur, the Final State is entered whereby tracing trigger alignment is defined by the TALIGN bit. If a tracing session is selected by the TSOURCE bit, breakpoints are requested when the tracing session has completed, thus if Begin aligned triggering is selected, the breakpoint is requested only on completion of the subsequent trace (see Table 6-42). If no tracing session is selected, breakpoints are requested immediately. TRIG breakpoints are possible with a single write to DBG1, setting ARM and TRIG simultaneously.

#### 6.4.7.3 Breakpoint Priorities

If a TRIG trigger occurs after Begin aligned tracing has already started, then the TRIG no longer has an effect. When the associated tracing session is complete, the breakpoint occurs. Similarly if a TRIG is followed by a subsequent comparator channel match, it has no effect, since tracing has already started.

If a forced SWI breakpoint coincides with a BGND in user code with BDM enabled, then the BDM is activated by the BGND and the breakpoint to SWI is suppressed.

#### 6.4.7.3.1 DBG Breakpoint Priorities And BDM Interfacing

Breakpoint operation is dependent on the state of the BDM module. If the BDM module is active, the CPU is executing out of BDM firmware, thus comparator matches and associated breakpoints are disabled. In addition, while executing a BDM TRACE command, tagging into BDM is disabled. If BDM is not active, the breakpoint gives priority to BDM requests over SWI requests if the breakpoint happens to coincide with a SWI instruction in user code. On returning from BDM, the SWI from user code gets executed.
BDM cannot be entered from a breakpoint unless the ENABLE bit is set in the BDM. If entry to BDM via a BGND instruction is attempted and the ENABLE bit in the BDM is cleared, the CPU actually executes the BDM firmware code, checks the ENABLE and returns if ENABLE is not set. If not serviced by the monitor then the breakpoint is re-asserted when the BDM returns to normal CPU flow.

If the comparator register contents coincide with the SWI/BDM vector address then an SWI in user code could coincide with a DBG breakpoint. The CPU ensures that BDM requests have a higher priority than SWI requests. Returning from the BDM/SWI service routine care must be taken to avoid a repeated breakpoint at the same address.

Should a tagged or forced breakpoint coincide with a BGND in user code, then the instruction that follows the BGND instruction is the first instruction executed when normal program execution resumes.

**NOTE**
When program control returns from a tagged breakpoint using an RTI or BDM GO command without program counter modification it returns to the instruction whose tag generated the breakpoint. To avoid a repeated breakpoint at the same location reconfigure the DBG module in the SWI routine, if configured for an SWI breakpoint, or over the BDM interface by executing a TRACE command before the GO to increment the program flow past the tagged instruction.

### 6.5 Application Information

#### 6.5.1 State Machine scenarios

Defining the state control registers as SCR1, SCR2, SCR3 and M0, M1, M2 as matches on channels 0, 1, 2 respectively. SCR encoding supported by S12SDBGV1 are shown in black. SCR encoding supported only in S12SDBGV2 are shown in red. For backwards compatibility the new scenarios use a 4th bit in each SCR register. Thus the existing encoding for SCRx[2:0] is not changed.

### 6.5.2 Scenario 1

A trigger is generated if a given sequence of 3 code events is executed.

**Figure 6-27. Scenario 1**

![Transition Diagram](image)

Scenario 1 is possible with S12SDBGV1 SCR encoding

### 6.5.3 Scenario 2

A trigger is generated if a given sequence of 2 code events is executed.

**Figure 6-28. Scenario 2a**

![Transition Diagram](image)

A trigger is generated if a given sequence of 2 code events is executed, whereby the first event is entry into a range (COMPA, COMPB configured for range mode). M1 is disabled in range modes.

**Figure 6-29. Scenario 2b**

![Transition Diagram](image)

A trigger is generated if a given sequence of 2 code events is executed, whereby the second event is entry into a range (COMPA, COMPB configured for range mode)

**Figure 6-30. Scenario 2c**

![Transition Diagram](image)

All 3 scenarios 2a, 2b, 2c are possible with the S12SDBGV1 SCR encoding
6.5.4 Scenario 3

A trigger is generated immediately when one of up to 3 given events occurs.

![Figure 6-31. Scenario 3](image)

Scenario 3 is possible with S12SDBGV1 SCR encoding.

6.5.5 Scenario 4

Trigger if a sequence of 2 events is carried out in an incorrect order. Event A must be followed by event B and event B must be followed by event A. 2 consecutive occurrences of event A without an intermediate event B cause a trigger. Similarly 2 consecutive occurrences of event B without an intermediate event A cause a trigger. This is possible by using CompA and CompC to match on the same address as shown.

![Figure 6-32. Scenario 4a](image)

This scenario is currently not possible using 2 comparators only. S12SDBGV2 makes it possible with 2 comparators, State 3 allowing a M0 to return to state 2, whilst a M2 leads to final state as shown.

![Figure 6-33. Scenario 4b (with 2 comparators)](image)

The advantage of using only 2 channels is that now range comparisons can be included (channel 0).
This however violates the S12SDBGV1 specification, which states that a match leading to final state always has priority in case of a simultaneous match, whilst priority is also given to the lowest channel number. For S12SDBG the corresponding CPU priority decoder is removed to support this, such that on simultaneous taghits, taghits pointing to final state have highest priority. If no taghit points to final state then the lowest channel number has priority. Thus with the above encoding from State3, the CPU and DBG would break on a simultaneous M0/M2.

### 6.5.6 Scenario 5

Trigger if following event A, event C precedes event B. i.e. the expected execution flow is A->B->C.

**Figure 6-34. Scenario 5**

Scenario 5 is possible with the S12SDBGV1 SCR encoding

### 6.5.7 Scenario 6

Trigger if event A occurs twice in succession before any of 2 other events (BC) occurs. This scenario is not possible using the S12SDBGV1 SCR encoding. S12SDBGV2 includes additions shown in red. The change in SCR1 encoding also has the advantage that a State1->State3 transition using M0 is now possible. This is advantageous because range and data bus comparisons use channel0 only.

**Figure 6-35. Scenario 6**

### 6.5.8 Scenario 7

Trigger when a series of 3 events is executed out of order. Specifying the event order as M1,M2,M0 to run in loops (120120120). Any deviation from that order should trigger. This scenario is not possible using the
S12SDBGV1 SCR encoding because OR possibilities are very limited in the channel encoding. By adding OR forks as shown in red this scenario is possible.

**Figure 6-36. Scenario 7**

On simultaneous matches the lowest channel number has priority so with this configuration the forking from State1 has the peculiar effect that a simultaneous match0/match1 transitions to final state but a simultaneous match2/match1 transitions to state2.

### 6.5.9 Scenario 8

Trigger when a routine/event at M2 follows either M1 or M0.

**Figure 6-37. Scenario 8a**

Trigger when an event M2 is followed by either event M0 or event M1

**Figure 6-38. Scenario 8b**

Scenario 8a and 8b are possible with the S12SDBGV1 and S12SDBGV2 SCR encoding
6.5.10 Scenario 9

Trigger when a routine/event at A (M2) does not follow either B or C (M1 or M0) before they are executed again. This cannot be realized with the S12SDBGV1 SCR encoding due to OR limitations. By changing the SCR2 encoding as shown in red this scenario becomes possible.

Figure 6-39. Scenario 9

```
SCR1=0111
State1
M2
M01
SCR2=1111
State2
M01
Final State
```

6.5.11 Scenario 10

Trigger if an event M0 occurs following up to two successive M2 events without the resetting event M1. As shown up to 2 consecutive M2 events are allowed, whereby a reset to State1 is possible after either one or two M2 events. If an event M0 occurs following the second M2, before M1 resets to State1 then a trigger is generated. Configuring CompA and CompC the same, it is possible to generate a breakpoint on the third consecutive occurrence of event M0 without a reset M1.

Final State
```

Scenario 10b shows the case that after M2 then M1 must occur before M0. Starting from a particular point in code, event M2 must always be followed by M1 before M0. If after any M2, event M0 occurs before M1 then a trigger is generated.

7.1 Introduction

This specification describes the function of the Clock, Reset and Power Management Unit (S12CPMU).

- The Pierce oscillator (OSCLCP) provides a robust, low-noise and low-power external clock source. It is designed for optimal start-up margin with typical crystal oscillators.
- The Voltage regulator (IVREG) operates from the range 3.13V to 5.5V. It provides all the required chip internal voltages and voltage monitors.
- The Phase Locked Loop (PLL) provides a highly accurate frequency multiplier with internal filter.
- The Internal Reference Clock (IRC1M) provides a 1MHz clock.

7.1.1 Features

The Pierce Oscillator (OSCLCP) contains circuitry to dynamically control current gain in the output amplitude. This ensures a signal with low harmonic distortion, low power and good noise immunity.

- Supports crystals or resonators from 4MHz to 16MHz.
S12 Clock, Reset and Power Management Unit (S12CPMU)

- High noise immunity due to input hysteresis and spike filtering.
- Low RF emissions with peak-to-peak swing limited dynamically
- Transconductance (gm) sized for optimum start-up margin for typical crystals
- Dynamic gain control eliminates the need for external current limiting resistor
- Integrated resistor eliminates the need for external bias resistor.
- Low power consumption: Operates from internal 1.8V (nominal) supply, Amplitude control limits power

The Voltage Regulator (IVREG) has the following features:
- Input voltage range from 3.13V to 5.5V
- Low-voltage detect (LVD) with low-voltage interrupt (LVI)
- Power-on reset (POR)
- Low-voltage reset (LVR)

The Phase Locked Loop (PLL) has the following features:
- highly accurate and phase locked frequency multiplier
- Configurable internal filter for best stability and lock time.
- Frequency modulation for defined jitter and reduced emission
- Automatic frequency lock detector
- Interrupt request on entry or exit from locked condition
- Reference clock either external (crystal) or internal square wave (1MHz IRC1M) based.
- PLL stability is sufficient for LIN communication, even if using IRC1M as reference clock

The Internal Reference Clock (IRC1M) has the following features:
- Trimmable in frequency
- Factory trimmed value for 1MHz in Flash Memory, can be overwritten by application if required

Other features of the S12CPMU include
- Clock monitor to detect loss of crystal
- Autonomous periodical interrupt (API)
- Bus Clock Generator
  - Clock switch to select either PLLCLK or external crystal/resonator based Bus Clock
  - PLLCLK divider to adjust system speed
- System Reset generation from the following possible sources:
  - Power-on reset (POR)
  - Low-voltage reset (LVR)
  - Illegal address access
  - COP time out
  - Loss of oscillation (clock monitor fail)
  - External pin RESET
7.1.2 Modes of Operation

This subsection lists and briefly describes all operating modes supported by the S12CPMU.

7.1.2.1 Run Mode

The voltage regulator is in Full Performance Mode (FPM).

The Phase Locked Loop (PLL) is on.

The Internal Reference Clock (IRC1M) is on.

The API is available.

- **PLL Engaged Internal (PEI)**
  - This is the default mode after System Reset and Power-On Reset.
  - The Bus Clock is based on the PLLCLK.
  - After reset the PLL is configured for 64MHz VCOCLK operation
    - Post divider is 0x03, so PLLCLK is VCOCLK divided by 4, that is 16MHz and Bus Clock is 8MHz.
    - The PLL can be re-configured for other bus frequencies.
  - The reference clock for the PLL (REFCLK) is based on internal reference clock IRC1M

- **PLL Engaged External (PEE)**
  - The Bus Clock is based on the PLLCLK.
  - This mode can be entered from default mode PEI by performing the following steps:
    - Configure the PLL for desired bus frequency.
    - Program the reference divider (REFDIV[3:0] bits) to divide down oscillator frequency if necessary.
    - Enable the external oscillator (OSCE bit)

- **PLL Bypassed External (PBE)**
  - The Bus Clock is based on the Oscillator Clock (OSCCLK).
  - This mode can be entered from default mode PEI by performing the following steps:
    - Enable the external oscillator (OSCE bit)
    - Wait for oscillator to start up (UPOSCon=1)
    - Select the Oscillator Clock (OSCCLK) as Bus Clock (PLLSEL=0).
  - The PLLCLK is still on to filter possible spikes of the external oscillator clock.

7.1.2.2 Wait Mode

For S12CPMU Wait Mode is the same as Run Mode.
7.1.2.3 Stop Mode

This mode is entered by executing the CPU STOP instruction.

The voltage regulator is in Reduced Power Mode (RPM).

The API is available.

The Phase Locked Loop (PLL) is off.

The Internal Reference Clock (IRC1M) is off.

Core Clock, Bus Clock and BDM Clock are stopped.

Depending on the setting of the PSTP and the OSCE bit, Stop Mode can be differentiated between Full Stop Mode (PSTP = 0 or OSCE=0) and Pseudo Stop Mode (PSTP = 1 and OSCE=1).

- **Full Stop Mode (PSTP=0 or OSCE=0)**
  
  The external oscillator (OSCLCP) is disabled.

  After wake-up from Full Stop Mode the Core Clock and Bus Clock are running on PLLCLK (PLLSEL=1). After wake-up from Full Stop Mode COP and RTI are running on IRCCLK (COPOSCSEL=0, RTIOSCSEL=0).

- **Pseudo Stop Mode (PSTP=1 and OSCE=1)**
  
  The external oscillator (OSCLCP) continues to run. If the respective enable bits are set the COP and RTI will continue to run.

  The clock configuration bits PLLSEL, COPOSCSEL, RTIOSCSEL are unchanged.

**NOTE**

When starting up the external oscillator (either by programming OSCE bit to 1 or on exit from Full Stop Mode with OSCE bit already 1) the software must wait for a minimum time equivalent to the startup-time of the external oscillator $t_{\text{UPOSC}}$ before entering Pseudo Stop Mode.
7.2 Signal Description

This section lists and describes the signals that connect off chip.

7.2.1 RESET

RESET is an active-low bidirectional pin. As an input it initializes the MCU asynchronously to a known start-up state. As an open-drain output it indicates that an MCU-internal reset has been triggered.

7.2.2 EXTAL and XTAL

These pins provide the interface for a crystal to control the internal clock generator circuitry. EXTAL is the external clock input or the input to the crystal oscillator amplifier. XTAL is the output of the crystal oscillator amplifier. The MCU internal OSCCLK is derived from the EXTAL input frequency. If OSCE=0,
the EXTAL pin is pulled down by an internal resistor of approximately 200 kΩ and the XTAL pin is pulled down by an internal resistor of approximately 700 kΩ.

**NOTE**
Freescale recommends an evaluation of the application board and chosen resonator or crystal by the resonator or crystal supplier.
Loop controlled circuit is not suited for overtone resonators and crystals.

### 7.2.3 TEMPSENSE — temperature sensor output voltage
Depending on the VSEL value either the voltage level generated by the temperature sensor or the VREG bandgap voltage is driven to a special channel of the ATD Converter. See device level specification for connectivity.

### 7.2.4 VDDR — Regulator Power Input Pin
VDDR is the power input of IVREG. All currents sourced into the regulator loads flow through this pin. A chip external decoupling capacitor (100 nF...220 nF, X7R ceramic) between VDDR and VSS can smooth ripple on VDDR.

### 7.2.5 VDDA, VSSA — Regulator Reference Supply Pins
VDDA/VSSA which are relatively quiet, are used to supply the analog parts of the regulator. Internal precision reference circuits are supplied from these signals. A chip external decoupling capacitor (100 nF...220 nF, X7R ceramic) between VDDA and VSSA can further improve the quality of this supply.

### 7.2.6 VSS, VSSPLL— Ground Pins
VSS and VSSPLL must be grounded.

### 7.2.7 VDDX, VSSX— Pad Supply Pins
This supply domain is monitored by the Low Voltage Reset circuit.
An off-chip decoupling capacitor (100 nF...220 nF, X7R ceramic) between VDDX and VSSX can further improve the quality of this supply.

### 7.2.8 API_EXTCLK — API external clock output pin
This pin provides the signal selected via APIES and is enabled with APIEA bit. See device specification to which pin it connects.
7.3 Memory Map and Registers

This section provides a detailed description of all registers accessible in the S12CPMU.

7.3.1 Module Memory Map

The S12CPMU registers are shown in Figure 7-3.

**Figure 7-3. CPMU Register Summary**
7.3.2 Register Descriptions

This section describes all the S12CPMU registers and their individual bits.

Address order is as listed in Figure 7-3.

7.3.2.1 S12CPMU Synthesizer Register (CPMUSYNR)

The CPMUSYNR register controls the multiplication factor of the PLL and selects the VCO frequency range.

Read: Anytime
Write: If PROT=0 (CPMUPROT register) and PLLSEL=1 (CPMUCLKS register), then write anytime. Else write has no effect.

**NOTE**

Writing to this register clears the LOCK and UPOSC status bits.

If PLL has locked (LOCK=1)

\[ f_{VCO} = 2 \times f_{\text{REF}} \times (\text{SYNDIV} + 1) \]

**NOTE**

\( f_{VCO} \) must be within the specified VCO frequency lock range. Bus frequency \( f_{\text{bus}} \) must not exceed the specified maximum.

The VCOFRQ[1:0] bits are used to configure the VCO gain for optimal stability and lock time. For correct PLL operation the VCOFRQ[1:0] bits have to be selected according to the actual target VCOCLK frequency as shown in Table 7-1. Setting the VCOFRQ[1:0] bits incorrectly can result in a non functional PLL (no locking and/or insufficient stability).

**Table 7-1. VCO Clock Frequency Selection**

<table>
<thead>
<tr>
<th>VCOCLK Frequency Ranges</th>
<th>VCOFRQ[1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>32MHz ( \leq f_{VCO} \leq 48MHz )</td>
<td>00</td>
</tr>
<tr>
<td>48MHz ( &lt; f_{VCO} \leq 64MHz )</td>
<td>01</td>
</tr>
<tr>
<td>Reserved</td>
<td>10</td>
</tr>
<tr>
<td>Reserved</td>
<td>11</td>
</tr>
</tbody>
</table>
7.3.2.2 S12CPMU Reference Divider Register (CPMUREFDIV)

The CPMUREFDIV register provides a finer granularity for the PLL multiplier steps when using the external oscillator as reference.

The REFFRQ[1:0] bits are used to configure the internal PLL filter for optimal stability and lock time. For correct PLL operation the REFFRQ[1:0] bits have to be selected according to the actual REFCLK frequency as shown in Table 7-2.

If IRC1M is selected as REFCLK (OSCE=0) the PLL filter is fixed configured for the 1MHz <= fREF <= 2MHz range. The bits can still be written but will have no effect on the PLL filter configuration.

For OSCE=1, setting the REFFRQ[1:0] bits incorrectly can result in a non functional PLL (no locking and/or insufficient stability).

Table 7-2. Reference Clock Frequency Selection if OSC_LCP is enabled

<table>
<thead>
<tr>
<th>REFCLK Frequency Ranges (OSCE=1)</th>
<th>REFFRQ[1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>1MHz &lt;= fREF &lt;= 2MHz</td>
<td>00</td>
</tr>
<tr>
<td>2MHz &lt; fREF &lt;= 6MHz</td>
<td>01</td>
</tr>
<tr>
<td>6MHz &lt; fREF &lt;= 12MHz</td>
<td>10</td>
</tr>
<tr>
<td>fREF &gt;12MHz</td>
<td>11</td>
</tr>
</tbody>
</table>

NOTE
Write to this register clears the LOCK and UPOSC status bits.

\[ f_{REF} = \frac{f_{OSC}}{(REFDIV + 1)} \]

If OSCLCP is enabled (OSCE=1)

If OSCLCP is disabled (OSCE=0)

The REFFRQ[1:0] bits are used to configure the internal PLL filter for optimal stability and lock time. For correct PLL operation the REFFRQ[1:0] bits have to be selected according to the actual REFCLK frequency as shown in Table 7-2.

If IRC1M is selected as REFCLK (OSCE=0) the PLL filter is fixed configured for the 1MHz <= fREF <= 2MHz range. The bits can still be written but will have no effect on the PLL filter configuration.

For OSCE=1, setting the REFFRQ[1:0] bits incorrectly can result in a non functional PLL (no locking and/or insufficient stability).
7.3.2.3 S12CPMU Post Divider Register (CPMUPOSTDIV)

The POSTDIV register controls the frequency ratio between the VCOCLK and the PLLCLK.

Read: Anytime

Write: If PLLSEL=1 write anytime, else write has no effect.

If PLL is locked (LOCK=1) \[ f_{PLL} = \frac{f_{VCO}}{(POSTDIV + 1)} \]

If PLL is not locked (LOCK=0) \[ f_{PLL} = \frac{f_{VCO}}{4} \]

If PLL is selected (PLLSEL=1) \[ f_{bus} = \frac{f_{PLL}}{2} \]

7.3.2.4 S12CPMU Flags Register (CPMUFLG)

This register provides S12CPMU status bits and flags.

Read: Anytime

1. PORF is set to 1 when a power on reset occurs. Unaffected by System Reset.
2. LVRF is set to 1 when a low voltage reset occurs. Unaffected by System Reset. Set by power on reset.
3. ILAF is set to 1 when an illegal address reset occurs. Unaffected by System Reset. Cleared by power on reset.

Figure 7-6. S12CPMU Post Divider Register (CPMUPOSTDIV)

Figure 7-7. S12CPMU Flags Register (CPMUFLG)
Write: Refer to each bit for individual write conditions

### Table 7-3. CPMUFLG Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 RTIF | **Real Time Interrupt Flag** — RTIF is set to 1 at the end of the RTI period. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (RTIE=1), RTIF causes an interrupt request.  
0 RTI time-out has not yet occurred.  
1 RTI time-out has occurred. |
| 6 PORF | **Power on Reset Flag** — PORF is set to 1 when a power on reset occurs. This flag can only be cleared by writing a 1. Writing a 0 has no effect.  
0 Power on reset has not occurred.  
1 Power on reset has occurred. |
| 5 LVRF | **Low Voltage Reset Flag** — LVRF is set to 1 when a low voltage reset occurs. This flag can only be cleared by writing a 1. Low voltage reset has not occurred.  
0 Low voltage reset has not occurred.  
1 Low voltage reset has occurred. |
| 4 LOCKIF | **PLL Lock Interrupt Flag** — LOCKIF is set to 1 when LOCK status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (LOCKIE=1), LOCKIF causes an interrupt request.  
0 No change in LOCK bit.  
1 LOCK bit has changed. |
| 3 LOCK | **Lock Status Bit** — LOCK reflects the current state of PLL lock condition. Writes have no effect. While PLL is unlocked (LOCK=0) \( f_{PLL} = f_{VCO} / 4 \) to protect the system from high core clock frequencies during the PLL stabilization time tlock.  
0 VCOCLK is not within the desired tolerance of the target frequency.  
1 VCOCLK is within the desired tolerance of the target frequency.  
\( f_{PLL} = f_{VCO}/(POSTDIV+1) \). |
| 2 ILAF | **Illegal Address Reset Flag** — ILAF is set to 1 when an illegal address reset occurs. Refer to MMC chapter for details. This flag can only be cleared by writing a 1. Writing a 0 has no effect.  
0 Illegal address reset has not occurred.  
1 Illegal address reset has occurred. |
| 1 OSCIF | **Oscillator Interrupt Flag** — OSCIF is set to 1 when UPOSC status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (OSCIE=1), OSCIF causes an interrupt request.  
0 No change in UPOSC bit.  
1 UPOSC bit has changed. |
| 0 UPOSC | **Oscillator Status Bit** — UPOSC reflects the status of the oscillator. Writes have no effect. While UPOSC=0 the OSCCLK going to the MSCAN module is off. Entering Full Stop Mode UPOSC is cleared.  
0 The oscillator is off or oscillation is not qualified by the PLL.  
1 The oscillator is qualified by the PLL. |

**NOTE**

The adaptive spike filter uses the VCO clock as a reference to continuously qualify the external oscillator clock. Because of this, the PLL is always active and a valid PLL configuration is required for the system to work properly. Furthermore, the adaptive spike filter is used to determine the status of the external oscillator (reflected in the UPOSC bit). Since this function also relies on the VCO clock, loosing PLL lock status (LOCK=0, except for entering Pseudo Stop Mode) means loosing the oscillator status information as well (UPOSC=0).
7.3.2.5  S12CPMU Interrupt Enable Register (CPMUINT)

This register enables S12CPMU interrupt requests.

0x0038

<table>

7.3.2.6 S12CPMU Clock Select Register (CPMUCLKS)

This register controls S12CPMU clock selection.

0x0039

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 PLLSEL | PLL Select Bit  
This bit selects the PLLCLK as source of the System Clocks (Core Clock and Bus Clock).  
PLLSEL can only be set to 0, if UPOSC=1.  
UPOSC= 0 sets the PLLSEL bit.  
Entering Full Stop Mode sets the PLLSEL bit.  
0 System clocks are derived from OSCCLK if oscillator is up (UPOSC=1, fbus = fosc / 2.  
1 System clocks are derived from PLLCLK, fbus = fPLL / 2. |
| 6 PSTP | Pseudo Stop Bit  
This bit controls the functionality of the oscillator during Stop Mode.  
0 Oscillator is disabled in Stop Mode (Full Stop Mode).  
1 Oscillator continues to run in Stop Mode (Pseudo Stop Mode), option to run RTI and COP.  
Note: Pseudo Stop Mode allows for faster STOP recovery and reduces the mechanical stress and aging of the resonator in case of frequent STOP conditions at the expense of a slightly increased power consumption.  
Note: When starting up the external oscillator (either by programming OSCE bit to 1 or on exit from Full Stop Mode with OSCE bit is already 1) the software must wait for a minimum time equivalent to the startup-time of the external oscillator fUPOSC before entering Pseudo Stop Mode. |
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| PRE | RTI Enable During Pseudo Stop Bit — PRE enables the RTI during Pseudo Stop Mode.  
0 RTI stops running during Pseudo Stop Mode.  
1 RTI continues running during Pseudo Stop Mode if RTIOSCSEL=1.  
**Note:** If PRE=0 or RTIOSCSEL=0 then the RTI will go static while Stop Mode is active. The RTI counter will **not** be reset. |
| PCE | COP Enable During Pseudo Stop Bit — PCE enables the COP during Pseudo Stop Mode.  
0 COP stops running during Pseudo Stop Mode  
1 COP continues running during Pseudo Stop Mode if COPOSCSEL=1  
**Note:** If PCE=0 or COPOSCSEL=0 then the COP will go static while Stop Mode is active. The COP counter will **not** be reset. |
| RTIOSCSEL | RTI Clock Select — RTIOSCSEL selects the clock source to the RTI. Either IRCCLK or OSCCLK. Changing the RTIOSCSEL bit re-starts the RTI time-out period.  
RTIOSCSEL can only be set to 1, if UPOSC=1.  
UPOSC= 0 clears the RTIOSCSEL bit.  
0 RTI clock source is IRCCLK.  
1 RTI clock source is OSCCLK. |
| COPOSCSEL | COP Clock Select — COPOSCSEL selects the clock source to the COP. Either IRCCLK or OSCCLK. Changing the COPOSCSEL bit re-starts the COP time-out period.  
COPOSCSEL can only be set to 1, if UPOSC=1.  
UPOSC= 0 clears the COPOSCSEL bit.  
0 COP clock source is IRCCLK.  
1 COP clock source is OSCCLK. |
7.3.2.7 **S12CPMU PLL Control Register (CPMUPPLL)**

This register controls the PLL functionality.

<table>

*NOTE*

Write to this register clears the LOCK and UPOSC status bits.

*NOTE*

Care should be taken to ensure that the bus frequency does not exceed the specified maximum when frequency modulation is enabled.

*NOTE*

The frequency modulation (FM1 and FM0) can not be used if the Oscillator Filter is enabled.

**Figure 7-10. S12CPMU PLL Control Register (CPMUPPLL)**

Read: Anytime

Write: Anytime if PROT=0 (CPMUPROT register) and PLLSEL=1 (CPMUCLKS register). Else write has no effect.
S12CPMU RTI Control Register (CPMURTI)

This register selects the time-out period for the Real Time Interrupt.

The clock source for the RTI is either IRCCLK or OSCCLK depending on the setting of the RTIOSCSEL bit. In Stop Mode with PSTP=1 (Pseudo Stop Mode) and RTIOSCSEL=1 the RTI continues to run, else the RTI counter halts in Stop Mode.

7.3.2.9  **S12CPMU COP Control Register (CPMUCOP)**

This register controls the COP (Computer Operating Properly) watchdog.

The clock source for the COP is either IRCCLK or OSCCLK depending on the setting of the COPOSCSEL bit. In Stop Mode with PSTP=1 (Pseudo Stop Mode), COPOSCSEL=1 and PCE=1 the COP continues to run, else the COP counter halts in Stop Mode.

**Read:** Anytime

**Write:**
1. RSBCK: anytime in special mode; write to “1” but not to “0” in normal mode
2. WCOP, CR2, CR1, CR0:
   - Anytime in special mode, when WRTMASK is 0, otherwise it has no effect
   - Write once in normal mode, when WRTMASK is 0, otherwise it has no effect.
     - Writing CR[2:0] to “000” has no effect, but counts for the “write once” condition.
     - Writing WCOP to “0” has no effect, but counts for the “write once” condition.

When a non-zero value is loaded from Flash to CR[2:0] the COP time-out period is started.

A change of the COPOSCSEL bit (writing a different value or loosing UPOSC status) re-starts the COP time-out period.

In normal mode the COP time-out period is restarted if either of these conditions is true:
1. Writing a non-zero value to CR[2:0] (anytime in special mode, once in normal mode) with WRTMASK = 0.
2. Writing WCOP bit (anytime in special mode, once in normal mode) with WRTMASK = 0.
3. Changing RSBCK bit from “0” to “1”.

In special mode, any write access to CPMUCOP register restarts the COP time-out period.
Table 7-11. CPMUCOP Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 WCOP</td>
<td><strong>Window COP Mode Bit</strong> — When set, a write to the CP/MUARM COP register must occur in the last 25% of the selected period. A write during the first 75% of the selected period generates a COP reset. As long as all writes occur during this window, $55 can be written as often as desired. Once $AA is written after the $55, the time-out logic restarts and the user must wait until the next window before writing to CP/MUARM COP. Table 7-12 shows the duration of this window for the seven available COP rates.</td>
</tr>
<tr>
<td>6 RSBCK</td>
<td><strong>COP and RTI Stop in Active BDM Mode Bit</strong></td>
</tr>
<tr>
<td>5 WRTMASK</td>
<td><strong>Write Mask for WCOP and CR[2:0] Bit</strong> — This write-only bit serves as a mask for the WCOP and CR[2:0] bits while writing the CP/MUARM COP register. It is intended for BDM writing the RSBCK without changing the content of WCOP and CR[2:0].</td>
</tr>
<tr>
<td>2–0 CR[2:0]</td>
<td><strong>COP Watchdog Timer Rate Select</strong> — These bits select the COP time-out rate (see Table 7-12). Writing a nonzero value to CR[2:0] enables the COP counter and starts the time-out period. A COP counter time-out causes a System Reset. This can be avoided by periodically (before time-out) initializing the COP counter via the CP/MUARM COP register. While all of the following four conditions are true the CR[2:0], WCOP bits are ignored and the COP operates at highest time-out period (2 $2^{24}$ cycles) in normal COP mode (Window COP mode disabled):</td>

7.3.2.12  **S12CPMU COP Timer Arm/Reset Register (CPMUARMCOP)**

This register is used to restart the COP time-out period.

![Figure 7-15. S12CPMU CPMUARMCOP Register](image)

Read: Always reads $00

Write: Anytime

When the COP is disabled (CR[2:0] = "000") writing to this register has no effect.

When the COP is enabled by setting CR[2:0] nonzero, the following applies:

Writing any value other than $55 or $AA causes a COP reset. To restart the COP time-out period write $55 followed by a write of $AA. These writes do not need to occur back-to-back, but the sequence ($55, $AA) must be completed prior to COP end of time-out period to avoid a COP reset. Sequences of $55 writes are allowed. When the WCOP bit is set, $55 and $AA writes must be done in the last 25% of the selected time-out period; writing any value in the first 75% of the selected period will cause a COP reset.

7.3.2.13  **High Temperature Control Register (CPMUHTCTL)**

The CPMUHTCTL register configures the temperature sense features.

</tr>
<tr>
<td>9-0 IRCTRIM[9:0]</td>
<td>IRC1M Frequency Trim Bits — Trim bits for Internal Reference Clock</td>
</tr>
</tbody>
</table>

The frequency trimming consists of two different trimming methods:

A rough trimming controlled by bits IRCTRIM[9:6] can be done with frequency leaps of about 6% in average.

A fine trimming controlled by the bits IRCTRIM[5:0] can be done with frequency leaps of about 0.3% (this trimming determines the precision of the frequency setting of 0.15%, i.e. 0.3% is the distance between two trimming values).

Figure 7-26 shows the relationship between the trim bits and the resulting IRC1M frequency.
Figure 7-26. IRC1M Frequency Trimming Diagram
Figure 7-27. Influence of TCTRIM[3:0] on the Temperature Coefficient

NOTE

The frequency is not necessarily linear with the temperature (in most cases it will not be). The above diagram is meant only to give the direction (positive or negative) of the variation of the TC, relative to the nominal TC.

Setting TCTRIM[3:0] to 0x0000 or 0x1000 does not mean that the temperature coefficient will be zero. These two combinations basically switch off the TC compensation module, which results in the nominal TC of the IRC1M.

<td>+4.8%</td>
</tr>
<tr>
<td>1111</td>
<td>+3.62%</td>
<td>+5.5%</td>
</tr>
</tbody>
</table>

**NOTE**

Since the IRC1M frequency is not a linear function of the temperature, but more like a parabola, the above relative TC variation is only an indication and should be considered with care.

Be aware that the output frequency vary with TC trimming. A frequency trimming correction is therefore necessary. The values provided in Table 7-21 are typical values at ambient temperature which can vary from device to device.
7.3.2.21 S12CPMU Oscillator Register (CPMUOSC)

7.4 Functional Description

7.4.1 Phase Locked Loop with Internal Filter (PLL)

The PLL is used to generate a high speed PLLCLK based on a low frequency REFCLK.

The REFCLK is by default the IRCCLK which is trimmed to \( f_{IRC1M, TRIM} = 1\text{MHz} \).

If using the oscillator (OSCE=1) REFCLK will be based on OSCCLK. For increased flexibility, OSCCLK can be divided in a range of 1 to 16 to generate the reference frequency REFCLK using the REFDIV[3:0] bits. Based on the SYNDIV[5:0] bits the PLL generates the VCOCLK by multiplying the reference clock by a 2, 4, 6,... 126, 128. Based on the POSTDIV[4:0] bits the VCOCLK can be divided in a range of 1, 2, 3, 4, 5, 6,... to 32 to generate the PLLCLK.

\[
\begin{align*}
\text{If oscillator is enabled (OSCE=1)} & & f_{\text{REF}} = \frac{f_{\text{OSC}}}{(\text{REFDIV} + 1)} \\
\text{If oscillator is disabled (OSCE=0)} & & f_{\text{REF}} = f_{\text{IRC1M}} \\
\end{align*}
\]

\[
\begin{align*}
f_{\text{VCO}} &= 2 \times f_{\text{REF}} \times (\text{SYNDIV} + 1) \\
\text{If PLL is locked (LOCK=1)} & & f_{\text{PLL}} = \frac{f_{\text{VCO}}}{(\text{POSTDIV} + 1)} \\
\text{If PLL is not locked (LOCK=0)} & & f_{\text{PLL}} = \frac{f_{\text{VCO}}}{4} \\
\text{If PLL is selected (PLLSEL=1)} & & f_{\text{bus}} = \frac{f_{\text{PLL}}}{2} \\
\end{align*}
\]

**NOTE**

Although it is possible to set the dividers to command a very high clock frequency, do not exceed the specified bus frequency limit for the MCU.
Several examples of PLL divider settings are shown in Table 7-23. The following rules help to achieve optimum stability and shortest lock time:

- Use lowest possible $f_{VCO} / f_{REF}$ ratio (SYNDIV value).
- Use highest possible REFCLK frequency $f_{REF}$.

</tbody>
</table>

The phase detector inside the PLL compares the feedback clock ($FBCLK = VCOCLK/(SYNDIV+1)$) with the reference clock ($REFCLK = IRC1M or OSCCLK/REFDIV+1$)). Correction pulses are generated based on the phase difference between the two signals. The loop filter alters the DC voltage on the internal filter capacitor, based on the width and direction of the correction pulse, which leads to a higher or lower VCO frequency.

The user must select the range of the REFCLK frequency (REFFRQ[1:0] bits) and the range of the VCOCLK frequency (VCOFRQ[1:0] bits) to ensure that the correct PLL loop bandwidth is set.

The lock detector compares the frequencies of the FBCLK and the REFCLK. Therefore the speed of the lock detector is directly proportional to the reference clock frequency. The circuit determines the lock condition based on this comparison.

If PLL LOCK interrupt requests are enabled, the software can wait for an interrupt request and for instance check the LOCK bit. If interrupt requests are disabled, software can poll the LOCK bit continuously (during PLL start-up) or at periodic intervals. In either case, only when the LOCK bit is set, the VCOCLK will have stabilized to the programmed frequency.

- The LOCK bit is a read-only indicator of the locked state of the PLL.
- The LOCK bit is set when the VCO frequency is within the tolerance $\Delta_{\text{Lock}}$ and is cleared when the VCO frequency is out of the tolerance $\Delta_{\text{unl}}$.
- Interrupt requests can occur if enabled (LOCKIE = 1) when the lock condition changes, toggling the LOCK bit.
7.4.2 Startup from Reset

An example of startup of clock system from Reset is given in Figure 7-31.

Figure 7-31. Startup of clock system after Reset

7.4.3 Stop Mode using PLLCLK as Bus Clock

An example of what happens going into Stop Mode and exiting Stop Mode after an interrupt is shown in Figure 7-32. Disable PLL Lock interrupt (LOCKIE=0) before going into Stop Mode.

Figure 7-32. Stop Mode using PLLCLK as Bus Clock
7.4.4 Full Stop Mode using Oscillator Clock as Bus Clock

An example of what happens going into Full Stop Mode and exiting Full Stop Mode after an interrupt is shown in Figure 7-33.

Disable PLL Lock interrupt (LOCKIE=0) and oscillator status change interrupt (OSCIE=0) before going into Full Stop Mode.

7.4.5.1  Enabling the External Oscillator

An example of how to use the oscillator as Bus Clock is shown in Figure 7-34.

Figure 7-34. Enabling the External Oscillator

- Enable external oscillator by writing OSCE bit to one.
- Crystal/resonator starts oscillating.
- UPOSC flag is set upon successful start of oscillation.
- Select OSCCLK as Core/Bus Clock by writing PLLSEL to zero.
- Clock based on PLLCLK, based on OSCCLK.
7.4.5.2 The Adaptive Oscillator Filter

A spike in the oscillator clock can disturb the function of the modules driven by this clock.

The adaptive Oscillator Filter includes two features:

1. Filter noise (spikes) from the incoming external oscillator clock. The filter function is illustrated in Figure 7-35.

   Figure 7-35. Noise filtered by the Adaptive Oscillator Filter

   ![Diagram of noise filtered by the Adaptive Oscillator Filter]

2. Detect severe noise disturbances on the external oscillator clock, which cannot be filtered and indicate the critical situation to the software by clearing the UPOSC and LOCK status bit and setting the OSCIF and LOCKIF flag. An example for the detection of critical noise is illustrated in Figure 7-36.

   Figure 7-36. Critical noise detected by the Adaptive Oscillator Filter

   ![Diagram of critical noise detected by the Adaptive Oscillator Filter]

**NOTE**

If the LOCK bit is clear due to severe noise disturbance on the external oscillator clock the PLLCLK is derived from the VCO clock (with its actual frequency) divided by four (see also Section 7.3.2.3, “S12CPMU Post Divider Register (CPMUPOSTDIV)”)
The use of the filter function is only possible if the VCOCLK-to-OSCCLK ratio divided by two \( (f_{VCO} / f_{OSC})/2 \) is an integer number. This integer value must be written to the OSCFILT[4:0] bits.

If enabled, the oscillator filter is sampling the incoming oscillator clock signal (EXTAL) with the VCOCLK frequency.

Using VCOCLK, a time window is defined during which an edge of the OSCCLK is expected. In case of OSCBW = 1 the width of this window is three VCOCLK cycles, if the OSCBW = 0 it is one VCOCLK cycle.

The noise detection is active for certain combinations of OSCFILT[4:0] and OSCBW bit settings as shown in Table 7-24

**Table 7-24. Noise Detection Settings**

<table>

<tr>
<td></td>
<td>1</td>
<td>disabled</td>
<td>active</td>
</tr>
<tr>
<td>&gt;=4</td>
<td>x</td>
<td>active</td>
<td>active</td>
</tr>
</tbody>
</table>

**NOTE**

If the VCOCLK frequency is higher than 25 MHz the wide bandwidth must be selected (OSCBW = 1).
7.4.6  System Clock Configurations

7.4.6.1  PLL Engaged Internal Mode (PEI)

This mode is the default mode after System Reset or Power-On Reset.

The Bus Clock is based on the PLLCLK, the reference clock for the PLL is internally generated (IRC1M). The PLL is configured to 64 MHz VCOCLK with POSTDIV set to 0x03. If locked (LOCK=1) this results in a PLLCLK of 16 MHz and a Bus Clock of 8 MHz. The PLL can be re-configured to other bus frequencies.

The clock sources for COP and RTI are based on the internal reference clock generator (IRC1M).

7.4.6.2  PLL Engaged External Mode (PEE)

In this mode, the Bus Clock is based on the PLLCLK as well (like PEI). The reference clock for the PLL is based on the external oscillator. The adaptive spike filter and detection logic which uses the VCOCLK to filter and qualify the external oscillator clock can be enabled.

The clock sources for COP and RTI can be based on the internal reference clock generator or on the external oscillator clock.

This mode can be entered from default mode PEI by performing the following steps:

1. Configure the PLL for desired bus frequency.
2. Optionally the adaptive spike filter and detection logic can be enabled by calculating the integer value for the OSCFIL[4:0] bits and setting the bandwidth (OSCBW) accordingly.
3. Enable the external oscillator (OSCE bit).
4. Wait for the PLL being locked (LOCK = 1) and the oscillator to start-up and additionally being qualified if the adaptive spike filter is enabled (UPOSC =1).
5. Clear all flags in the CPMUFLG register to be able to detect any future status bit change.
6. Optionally status interrupts can be enabled (CPMUINT register).

Since the adaptive spike filter (filter and detection logic) uses the VCOCLK to continuously filter and qualify the external oscillator clock, loosing PLL lock status (LOCK=0) means loosing the oscillator status information as well (UPOSC=0).

The impact of loosing the oscillator status in PEE mode is as follows:

• The PLLCLK is derived from the VCO clock (with its actual frequency) divided by four until the PLL locks again.

Application software needs to be prepared to deal with the impact of loosing the oscillator status at any time.
7.4.6.3 PLL Bypassed External Mode (PBE)

In this mode, the Bus Clock is based on the external oscillator clock. The reference clock for the PLL is based on the external oscillator. The adaptive spike filter and detection logic can be enabled which uses the VCOCLK to filter and qualify the external oscillator clock.

The clock sources for COP and RTI can be based on the internal reference clock generator or on the external oscillator clock.

This mode can be entered from default mode PEI by performing the following steps:

1. Make sure the PLL configuration is valid
2. Optionally the adaptive spike filter and detection logic can be enabled by calculating the integer value for the OSCFIL[4:0] bits and setting the bandwidth (OSCBW) accordingly.
3. Enable the external oscillator (OSCE bit)
4. Wait for the PLL being locked (LOCK = 1) and the oscillator to start-up and additionally being qualified if the adaptive spike filter is enabled (UPOSC =1).
5. Clear all flags in the CPMUFLG register to be able to detect any status bit change.
6. Optionally status interrupts can be enabled (CPMUINT register).
7. Select the Oscillator Clock (OSCCLK) as Bus Clock (PLLSEL=0)

Since the adaptive spike filter (filter and detection logic) uses VCOCLK (from PLL) to continuously filter and qualify the external oscillator clock, losing PLL lock status (LOCK=0) means losing the oscillator status information as well (UPOSC=0).

The impact of losing the oscillator status in PBE mode is as follows:

- PLLSEL is set automatically and the Bus Clock is switched back to the PLLCLK.
- The PLLCLK is derived from the VCO clock (with its actual frequency) divided by four until the PLL locks again.

Application software needs to be prepared to deal with the impact of losing the oscillator status at any time.

In the PBE mode, not every noise disturbance can be indicated by bits LOCK and UPOSC (both bits are based on the Bus Clock domain). There are clock disturbances possible, after which UPOSC and LOCK both stay asserted while occasional pauses on the filtered OSCCLK and resulting Bus Clock occur. The spike filter is still functional and protects the Bus Clock from frequency overshoot due to spikes on the external oscillator clock. The filtered OSCCLK and resulting Bus Clock will pause until the PLL has stabilized again.
7.5 Resets

7.5.1 General

<tr>
<td></td>
<td></td>
<td></td>
<td>External pin RESET</td>
</tr>
</tbody>
</table>

NOTE

While System Reset is asserted the PLLCLK runs with the frequency \( f_{VCORST} \).
The internal reset of the MCU remains asserted while the reset generator completes the 768 PLLCLK cycles long reset sequence. In case the \text{RESET} pin is externally driven low for more than these 768 PLLCLK cycles (External Reset), the internal reset remains asserted longer.

**Figure 7-37. RESET Timing**

### 7.5.2.1 Clock Monitor Reset

If the external oscillator is enabled (OSCE=1) in case of loss of oscillation or the oscillator frequency is below the failure assert frequency $f_{CMFA}$ (see device electrical characteristics for values), the S12CPMU generates a Clock Monitor Reset. In Full Stop Mode the external oscillator and the clock monitor are disabled.

### 7.5.2.2 Computer Operating Properly Watchdog (COP) Reset

The COP (free running watchdog timer) enables the user to check that a program is running and sequencing properly. When the COP is being used, software is responsible for keeping the COP from timing out. If the COP times out it is an indication that the software is no longer being executed in the intended sequence; thus COP reset is generated.

The clock source for the COP is either IRCCLK or OSCCLK depending on the setting of the COPOSCSEL bit. In Stop Mode with PSTP=1 (Pseudo Stop Mode), COPOSCSEL=1 and PCE=1 the COP continues to run, else the COP counter halts in Stop Mode.

Three control bits in the CPMUCOP register allow selection of seven COP time-out periods. When COP is enabled, the program must write $55$ and $AA$ (in this order) to the CPMUARMCOP register during the selected time-out period. Once this is done, the COP time-out period is restarted. If the program fails to do this and the COP times out, a COP reset is generated. Also, if any value other than $55$ or $AA$ is written, a COP reset generated.
Windowed COP operation is enabled by setting WCOP in the CPMUCOP register. In this mode, writes to the CPMUARMCOP register to clear the COP timer must occur in the last 25% of the selected time-out period. A premature write will immediately reset the part.

7.5.3 Power-On Reset (POR)

The on-chip POR circuitry detects when the internal supply V\textsubscript{DD} drops below an appropriate voltage level (voltage level not specified in this document because this supply is not visible on device pins). POR is deasserted, if the internal supply V\textsubscript{DD} exceeds an appropriate voltage level (voltage level not specified in this document because this supply is not visible on device pins).

7.5.4 Low-Voltage Reset (LVR)

The on-chip LVR circuitry detects when one of the supply voltages V\textsubscript{DD}, V\textsubscript{DDF} or V\textsubscript{DDX} drops below an appropriate voltage level. If LVR is deasserted the MCU is fully operational at the specified maximum speed. The LVR assert and deassert levels for the supply voltage V\textsubscript{DDX} are V\textsubscript{LVRXA} and V\textsubscript{LVRXD} and are specified in the device Reference Manual.

7.6 Interrupts

The interrupt/reset vectors requested by the S12CPMU are listed in Table 7-27. Refer to MCU specification for related vector addresses and priorities.

<table>
<thead>
<tr>
<th>Interrupt Source</th>

<tr>
<td>Autonomous Periodical Interrupt</td>
<td>I bit</td>
<td>CPMUAPICTL (APIE)</td>
</tr>
</tbody>
</table>

Table 7-27. S12CPMU Interrupt Vectors
7.6.1 Description of Interrupt Operation

7.6.1.1 Real Time Interrupt (RTI)

The clock source for the RTI is either IRCCLK or OSCCLK depending on the setting of the RTIOSCSEL bit. In Stop Mode with PSTP=1 (Pseudo Stop Mode), RTIOSCSEL=1 and PRE=1 the RTI continues to run, else the RTI counter halts in Stop Mode.

The RTI can be used to generate hardware interrupts at a fixed periodic rate. If enabled (by setting RTIE=1), this interrupt will occur at the rate selected by the CPMURTI register. At the end of the RTI time-out period the RTIF flag is set to one and a new RTI time-out period starts immediately. A write to the CPMURTI register restarts the RTI time-out period.

7.6.1.2 PLL Lock Interrupt

The S12CPMU generates a PLL Lock interrupt when the lock condition (LOCK status bit) of the PLL changes, either from a locked state to an unlocked state or vice versa. Lock interrupts are locally disabled by setting the LOCKIE bit to zero. The PLL Lock interrupt flag (LOCKIF) is set to 1 when the lock condition has changed, and is cleared to 0 by writing a 1 to the LOCKIF bit.

7.6.1.3 Oscillator Status Interrupt

The Oscillator Filter contains two different features:

1. Filter spikes of the external oscillator clock.
2. Qualify the external oscillator clock.

When the OSCE bit is 0, then UPOSC stays 0. When OSCE=1 and OSCFILT = 0, then the filter is transparent and no spikes are filtered. The UPOSC bit is then set after the LOCK bit is set.

Upon detection of a status change (UPOSC), that is an unqualified oscillation becomes qualified or vice versa, the OSCIF flag is set. Going into Full Stop Mode or disabling the oscillator can also cause a status change of UPOSC.

Also, since the oscillator filter is based on the PLLCLK, any change in PLL configuration or any other event which causes the PLL lock status to be cleared leads to a loss of the oscillator status information as well (UPOSC=0).

Oscillator status change interrupts are locally enabled with the OSCIE bit.

NOTE

loosing the oscillator status (UPOSC=0) affects the clock configuration of the system\(^1\). This needs to be dealt with in application software.

---

\(^1\) For details please refer to “7.4.6 System Clock Configurations”
7.6.1.4 Low-Voltage Interrupt (LVI)
In FPM the input voltage $V_{DDA}$ is monitored. Whenever $V_{DDA}$ drops below level $V_{LVI}$, the status bit LVDS is set to 1. On the other hand, LVDS is reset to 0 when $V_{DDA}$ rises above level $V_{LVID}$. An interrupt, indicated by flag LVIF = 1, is triggered by any change of the status bit LVDS if interrupt enable bit LVIE = 1.

7.6.1.5 HTI - High Temperature Interrupt
In FPM the junction temperature $T_J$ is monitored. Whenever $T_J$ exceeds level $T_{HTI}$, the status bit HTDS is set to 1. Vice versa, HTDS is reset to 0 when $T_J$ get below level $T_{HTID}$. An interrupt, indicated by flag HTIF = 1, is triggered by any change of the status bit HTDS, if interrupt enable bit HTIE = 1.

7.6.1.6 Autonomous Periodical Interrupt (API)
The API sub-block can generate periodical interrupts independent of the clock source of the MCU. To enable the timer, the bit APIFE needs to be set.

The API timer is either clocked by a trimmable internal RC oscillator (ACLK) or the Bus Clock. Timer operation will freeze when MCU clock source is selected and Bus Clock is turned off. The clock source can be selected with bit APICLK. APICLK can only be written when APIFE is not set.

The APIR[15:0] bits determine the interrupt period. APIR[15:0] can only be written when APIFE is cleared. As soon as APIFE is set, the timer starts running for the period selected by APIR[15:0] bits. When the configured time has elapsed, the flag APIF is set. An interrupt, indicated by flag APIF = 1, is triggered if interrupt enable bit APIE = 1. The timer is re-started automatically again after it has set APIF.

The procedure to change APICLK or APIR[15:0] is first to clear APIFE, then write to APICLK or APIR[15:0], and afterwards set APIFE.

The API Trimming bits APITR[5:0] must be set so the minimum period equals 0.2 ms if stable frequency is desired.

See Table 7-17 for the trimming effect of APITR.

**NOTE**
The first period after enabling the counter by APIFE might be reduced by API start up delay $t_{del}$.

It is possible to generate with the API a waveform at the external pin API_EXTCLK by setting APIFE and enabling the external access with setting APIEA.

8.1 Introduction

Freescale’s scalable controller area network (S12MSCANV3) definition is based on the MSCAN12 definition, which is the specific implementation of the MSCAN concept targeted for the M68HC12 microcontroller family.

The module is a communication controller implementing the CAN 2.0A/B protocol as defined in the Bosch specification dated September 1991. For users to fully understand the MSCAN specification, it is recommended that the Bosch specification be read first to familiarize the reader with the terms and concepts contained within this document.

Though not exclusively intended for automotive applications, CAN protocol is designed to meet the specific requirements of a vehicle serial data bus: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness, and required bandwidth.

MSCAN uses an advanced buffer arrangement resulting in predictable real-time behavior and simplified application software.

8.1.2 Block Diagram

![MSCAN Block Diagram](image)

Figure 8-1. MSCAN Block Diagram
8.1.3 Features

The basic features of the MSCAN are as follows:

- Implementation of the CAN protocol — Version 2.0A/B
  - Standard and extended data frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mbps\(^1\)
  - Support for remote frames
- Five receive buffers with FIFO storage scheme
- Three transmit buffers with internal prioritization using a “local priority” concept
- Flexible maskable identifier filter supports two full-size (32-bit) extended identifier filters, or four 16-bit filters, or eight 8-bit filters
- Programmable wakeup functionality with integrated low-pass filter
- Programmable loopback mode supports self-test operation
- Programmable listen-only mode for monitoring of CAN bus
- Programmable bus-off recovery functionality
- Separate signalling and interrupt capabilities for all CAN receiver and transmitter error states (warning, error passive, bus-off)
- Programmable MSCAN clock source either bus clock or oscillator clock
- Internal timer for time-stamping of received and transmitted messages
- Three low-power modes: sleep, power down, and MSCAN enable
- Global initialization of configuration registers

8.1.4 Modes of Operation

For a description of the specific MSCAN modes and the module operation related to the system operating modes refer to Section 8.4.4, “Modes of Operation”.

8.2 External Signal Description

The MSCAN uses two external pins.

**NOTE**

On MCUs with an integrated CAN physical interface (transceiver) the MSCAN interface is connected internally to the transceiver interface. In these cases the external availability of signals TXCAN and RXCAN is optional.

8.2.1 RXCAN — CAN Receiver Input Pin

RXCAN is the MSCAN receiver input pin.

1. Depending on the actual bit timing and the clock jitter of the PLL.
8.2.2 **TXCAN — CAN Transmitter Output Pin**

TXCAN is the MSCAN transmitter output pin. The TXCAN output pin represents the logic level on the CAN bus:

- 0 = Dominant state
- 1 = Recessive state

8.2.3 **CAN System**

A typical CAN system with MSCAN is shown in Figure 8-2. Each CAN station is connected physically to the CAN bus lines through a transceiver device. The transceiver is capable of driving the large current needed for the CAN bus and has current protection against defective CAN or defective stations.

![Figure 8-2. CAN System](image)

8.3 **Memory Map and Register Definition**

This section provides a detailed description of all registers accessible in the MSCAN.

8.3.1 **Module Memory Map**

Figure 8-3 gives an overview on all registers and their individual bits in the MSCAN memory map. The *register address* results from the addition of *base address* and *address offset*. The *base address* is determined at the MCU level and can be found in the MCU memory map description. The *address offset* is defined at the module level.

The MSCAN occupies 64 bytes in the memory space. The base address of the MSCAN module is determined at the MCU level when the MCU is defined. The register decode map is fixed and begins at the first address of the module address offset.
The detailed register descriptions follow in the order they appear in the register map.

Figure 8-3. MSCAN Register Summary
### Register Descriptions

This section describes in detail all the registers and register bits in the MSCAN module. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order. All bits of all registers in this module are completely synchronous to internal clocks during a register read.

#### 8.3.2.1 MSCAN Control Register 0 (CANCTL0)

The CANCTL0 register provides various control bits of the MSCAN module as described below.

---

= Unimplemented or Reserved
The CANCTL0 register, except WUPE, INITRQ, and SLPRQ, is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable again as soon as the initialization mode is exited (INITRQ = 0 and INITAK = 0).

### Table 8-3. CANCTL0 Register Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 RXFRM(1) | Received Frame Flag — This bit is read and clear only. It is set when a receiver has received a valid message correctly, independently of the filter configuration. After it is set, it remains set until cleared by software or reset. Clearing is done by writing a 1. Writing a 0 is ignored. This bit is not valid in loopback mode.  
0 No valid message was received since last clearing this flag  
1 A valid message was received since last clearing of this flag |
| 6 RXACT | Receiver Active Status — This read-only flag indicates the MSCAN is receiving a message. The flag is controlled by the receiver front end. This bit is not valid in loopback mode.  
0 MSCAN is transmitting or idle  
1 MSCAN is receiving a message (including when arbitration is lost)(2) |
| 5 CSWAI(3) | CAN Stops in Wait Mode — Enabling this bit allows for lower power consumption in wait mode by disabling all the clocks at the CPU bus interface to the MSCAN module.  
0 The module is not affected during wait mode  
1 The module ceases to be clocked during wait mode |
| 4 SYNCH | Synchronized Status — This read-only flag indicates whether the MSCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the MSCAN.  
0 MSCAN is not synchronized to the CAN bus  
1 MSCAN is synchronized to the CAN bus |
| 3 TIME | Timer Enable — This bit activates an internal 16-bit wide free running timer which is clocked by the bit clock rate. If the timer is enabled, a 16-bit time stamp will be assigned to each transmitted/received message within the active TX/RX buffer. Right after the EOF of a valid message on the CAN bus, the time stamp is written to the highest bytes (0x000E, 0x000F) in the appropriate buffer (see Section 8.3.3, “Programmer’s Model of Message Storage”). The internal timer is reset (all bits set to 0) when disabled. This bit is held low in initialization mode.  
0 Disable internal MSCAN timer  
1 Enable internal MSCAN timer |
Table 8-3. CANCTL0 Register Field Descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| WUPE(4) | Wake-Up Enable — This configuration bit allows the MSCAN to restart from sleep mode or from power down mode (entered from sleep) when traffic on CAN is detected (see Section 8.4.5.5, “MSCAN Sleep Mode”). This bit must be configured before sleep mode entry for the selected function to take effect.  
0 Wake-up disabled — The MSCAN ignores traffic on CAN  
1 Wake-up enabled — The MSCAN is able to restart |
| SLPRQ(5) | Sleep Mode Request — This bit requests the MSCAN to enter sleep mode, which is an internal power saving mode (see Section 8.4.5.5, “MSCAN Sleep Mode”). The sleep mode request is serviced when the CAN bus is idle, i.e., the module is not receiving a message and all transmit buffers are empty. The module indicates entry to sleep mode by setting SLPAK = 1 (see Section 8.3.2.2, “MSCAN Control Register 1 (CANCTL1)”). SLPRQ cannot be set while the WUPIF flag is set (see Section 8.3.2.5, “MSCAN Receiver Flag Register (CANRFLG)”). Sleep mode will be active until SLPRQ is cleared by the CPU or, depending on the setting of WUPE, the MSCAN detects activity on the CAN bus and clears SLPRQ itself.  
0 Running — The MSCAN functions normally  
1 Sleep mode request — The MSCAN enters sleep mode when CAN bus idle |
| INITRQ(6),(7) | Initialization Mode Request — When this bit is set by the CPU, the MSCAN skips to initialization mode (see Section 8.4.4.5, “MSCAN Initialization Mode”). Any ongoing transmission or reception is aborted and synchronization to the CAN bus is lost. The module indicates entry to initialization mode by setting INITAK = 1 (Section 8.3.2.2, “MSCAN Control Register 1 (CANCTL1)”). The following registers enter their hard reset state and restore their default values: CANCTLO(8), CANRFLG(9), CANRIER(10), CANTFLG, CANTIER, CANTARQ, CANTAAK, and CANTBSEL. The registers CANCTL1, CANBTR0, CANBTR1, CANIDAC, CANIDAR0-7, and CANIDMR0-7 can only be written by the CPU when the MSCAN is in initialization mode (INITRQ = 1 and INITAK = 1). The values of the error counters are not affected by initialization mode. When this bit is cleared by the CPU, the MSCAN restarts and then tries to synchronize to the CAN bus. If the MSCAN is not in bus-off state, it synchronizes after 11 consecutive recessive bits on the CAN bus; if the MSCAN is in bus-off state, it continues to wait for 128 occurrences of 11 consecutive recessive bits. Writing to other bits in CANCTL0, CANRFLG, CANRIER, CANTFLG, or CANTIER must be done only after initialization mode is exited, which is INITRQ = 0 and INITAK = 0.  
0 Normal operation  
1 MSCAN in initialization mode |

1. The MSCAN must be in normal mode for this bit to become set.  
2. See the Bosch CAN 2.0A/B specification for a detailed definition of transmitter and receiver states.  
3. In order to protect from accidentally violating the CAN protocol, TXCAN is immediately forced to a recessive state when the CPU enters wait (CSWAI = 1) or stop mode (see Section 8.4.5.2, “Operation in Wait Mode” and Section 8.4.5.3, “Operation in Stop Mode”).  
4. The CPU has to make sure that the WUPE register and the WUPIE wake-up interrupt enable register (see Section 8.3.2.6, “MSCAN Receiver Interrupt Enable Register (CANRIER)”) is enabled, if the recovery mechanism from stop or wait is required.  
5. The CPU cannot clear SLPRQ before the MSCAN has entered sleep mode (SLPRQ = 1 and SLPAK = 1).  
6. The CPU cannot clear INITRQ before the MSCAN has entered initialization mode (INITRQ = 1 and INITAK = 1).  
7. In order to protect from accidentally violating the CAN protocol, TXCAN is immediately forced to a recessive state when the initialization mode is requested by the CPU. Thus, the recommended procedure is to bring the MSCAN into sleep mode (SLPRQ = 1 and SLPAK = 1) before requesting initialization mode.  
8. Not including WUPE, INITRQ, and SLPRQ.  
9. TSTAT1 and TSTAT0 are not affected by initialization mode.  
10. RSTAT1 and RSTAT0 are not affected by initialization mode.  

---

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor
8.3.2.2 MSCAN Control Register 1 (CANCTL1)

The CANCTL1 register provides various control bits and handshake status information of the MSCAN module as described below.

![Figure 8-5. MSCAN Control Register 1 (CANCTL1)](image)

Table 8-4. CANCTL1 Register Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 CANE | MSCAN Enable  
0 MSCAN module is disabled  
1 MSCAN module is enabled |
| 6 CLKSRC | MSCAN Clock Source — This bit defines the clock source for the MSCAN module (only for systems with a clock generation module; Section 8.4.3.2, “Clock System,” and Section Figure 8-43., “MSCAN Clocking Scheme.”).  
0 MSCAN clock source is the oscillator clock  
1 MSCAN clock source is the bus clock |
| 5 LOOPB | Loopback Self Test Mode — When this bit is set, the MSCAN performs an internal loopback which can be used for self test operation. The bit stream output of the transmitter is fed back to the receiver internally. The RXCAN input is ignored and the TXCAN output goes to the recessive state (logic 1). The MSCAN behaves as it does normally when transmitting and treats its own transmitted message as a message received from a remote node. In this state, the MSCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.  
0 Loopback self test disabled  
1 Loopback self test enabled |
| 4 LISTEN | Listen Only Mode — This bit configures the MSCAN as a CAN bus monitor. When LISTEN is set, all valid CAN messages with matching ID are received, but no acknowledgement or error frames are sent out (see Section 8.4.4, “Listen-Only Mode”). In addition, the error counters are frozen. Listen only mode supports applications which require “hot plugging” or throughput analysis. The MSCAN is unable to transmit any messages when listen only mode is active.  
0 Normal operation  
1 Listen only mode activated |
| 3 BORM | Bus-Off Recovery Mode — This bit configures the bus-off state recovery mode of the MSCAN. Refer to Section 8.5.2, “Bus-Off Recovery,” for details.  
0 Automatic bus-off recovery (see Bosch CAN 2.0A/B protocol specification)  
1 Bus-off recovery upon user request |
8.3.2.3 MSCAN Bus Timing Register 0 (CANBTR0)

The CANBTR0 register configures various CAN bus timing parameters of the MSCAN module.

**Table 8-8. CANBTR1 Register Field Descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 0-7 SAMP | Sampling — This bit determines the number of CAN bus samples taken per bit time.  
  0 One sample per bit.  
  1 Three samples per bit\(^1\).  
  If SAMP = 0, the resulting bit value is equal to the value of the single bit positioned at the sample point. If SAMP = 1, the resulting bit value is determined by using majority rule on the three total samples. For higher bit rates, it is recommended that only one sample is taken per bit time (SAMP = 0). |
| 6-4 TSEG2[2:0] | Time Segment 2 — Time segments within the bit time fix the number of clock cycles per bit time and the location of the sample point (see Figure 8-44). Time segment 2 (TSEG2) values are programmable as shown in Table 8-9. |
| 3-0 TSEG1[3:0] | Time Segment 1 — Time segments within the bit time fix the number of clock cycles per bit time and the location of the sample point (see Figure 8-44). Time segment 1 (TSEG1) values are programmable as shown in Table 8-10. |
The bit time is determined by the oscillator frequency, the baud rate prescaler, and the number of time quanta (Tq) clock cycles per bit (as shown in Table 8-9 and Table 8-10).

\[ \text{Bit Time} = \frac{(\text{Prescaler value})}{f_{\text{CANCLK}}} \cdot (1 + \text{Time Segment 1} + \text{Time Segment 2}) \]

**8.3.2.5 MSCAN Receiver Flag Register (CANRFLG)**

A flag can be cleared only by software (writing a 1 to the corresponding bit position) when the condition which caused the setting is no longer valid. Every flag has an associated interrupt enable bit in the CANRIER register.
NOTE

The CANRFLG register is held in the reset state\(^1\) when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable again as soon as the initialization mode is exited (INITRQ = 0 and INITAK = 0).

### Table 8-11. CANRFLG Register Field Descriptions

<table>

<td><strong>WUPIF</strong></td>
</tr>
<tr>
<td>6</td>
<td><strong>CSCIF</strong></td>
</tr>
<tr>
<td>5-4</td>
<td><strong>RSTAT[1:0]</strong></td>
</tr>
</tbody>
</table>

**WUPIF**

-Wake-Up Interrupt Flag — If the MSCAN detects CAN bus activity while in sleep mode (see Section 8.4.5.5, “MSCAN Sleep Mode,”) and WUPE = 1 in CANTCTL0 (see Section 8.3.2.1, “MSCAN Control Register 0 (CANCTL0),”) the module will set WUPIF. If not masked, a wake-up interrupt is pending while this flag is set.

-0 No wake-up activity observed while in sleep mode
-1 MSCAN detected activity on the CAN bus and requested wake-up

**CSCIF**

-CAN Status Change Interrupt Flag — This flag is set when the MSCAN changes its current CAN bus status due to the actual value of the transmit error counter (TEC) and the receive error counter (REC). An additional 4-bit (RSTAT[1:0], TSTAT[1:0]) status register, which is split into separate sections for TEC/REC, informs the system on the actual CAN bus status (see Section 8.3.2.6, “MSCAN Receiver Interrupt Enable Register (CANRIER),”). If not masked, an error interrupt is pending while this flag is set. CSCIF provides a blocking interrupt. That guarantees that the receiver/transmitter status bits (RSTAT/TSTAT) are only updated when no CAN status change interrupt is pending. If the TECs/RECs change their current value after the CSCIF is asserted, which would cause an additional state change in the RSTAT/TSTAT bits, these bits keep their status until the current CSCIF interrupt is cleared again.

-0 No change in CAN bus status occurred since last interrupt
-1 MSCAN changed current CAN bus status

**RSTAT[1:0]**

-Receiver Status Bits — The values of the error counters control the actual CAN bus status of the MSCAN. As soon as the status change interrupt flag (CSCIF) is set, these bits indicate the appropriate receiver related CAN bus status of the MSCAN. The coding for the bits RSTAT1, RSTAT0 is:

-00 RxOK: 0 ≤ receive error counter ≤ 96
-01 RxWRN: 96 < receive error counter ≤ 127
-10 RxERR: 127 < receive error counter
-11 Bus-off\(^1\): transmit error counter > 255

1. The RSTAT[1:0], TSTAT[1:0] bits are not affected by initialization mode.
### MSCAN Receiver Interrupt Enable Register (CANRIER)

This register contains the interrupt enable bits for the interrupt flags described in the CANRFLG register.

**Fig. 8-9. MSCAN Receiver Interrupt Enable Register (CANRIER)**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 3-2     | **Transmitter Status Bits** — The values of the error counters control the actual CAN bus status of the MSCAN. As soon as the status change interrupt flag (CSCIF) is set, these bits indicate the appropriate transmitter related CAN bus status of the MSCAN. The coding for the bits TSTAT1, TSTAT0 is:  
| 00      | TxOK: 0 ≤ transmit error counter ≤ 96          |
| 01      | TxWRN: 96 < transmit error counter ≤ 127       |
| 10      | TxERR: 127 < transmit error counter ≤ 255      |
| 11      | Bus-Off: transmit error counter > 255          |
| 1       | **Overrun Interrupt Flag** — This flag is set when a data overrun condition occurs. If not masked, an error interrupt is pending while this flag is set.  
| 0       | No data overrun condition                      |
| 1       | A data overrun detected                        |
| 0       | **Receive Buffer Full Flag** — RXF is set by the MSCAN when a new message is shifted in the receiver FIFO. This flag indicates whether the shifted buffer is loaded with a correctly received message (matching identifier, matching cyclic redundancy code (CRC) and no other errors detected). After the CPU has read that message from the RxFG buffer in the receiver FIFO, the RXF flag must be cleared to release the buffer. A set RXF flag prohibits the shifting of the next FIFO entry into the foreground buffer (RxFG). If not masked, a receive interrupt is pending while this flag is set.  
| 0       | No new message available within the RxFG       |
| 1       | The receiver FIFO is not empty. A new message is available in the RxFG |

1. Redundant information for the most critical CAN bus status which is “bus-off”. This only occurs if the Tx error counter exceeds a number of 255 errors. Bus-off affects the receiver state. As soon as the transmitter leaves its bus-off state the receiver state skips to RxOK too. Refer also to TSTAT[1:0] coding in this register.

2. To ensure data integrity, do not read the receive buffer registers while the RXF flag is cleared. For MCUs with dual CPUs, reading the receive buffer registers while the RXF flag is cleared may result in a CPU fault condition.
8.3.2.7 MSCAN Transmitter Flag Register (CANTFLG)

The transmit buffer empty flags each have an associated interrupt enable bit in the CANTIER register.
NOTE

The CANTFLG register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Table 8-13. CANTFLG Register Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 2-0 TXE[2:0] | Transmitter Buffer Empty — This flag indicates that the associated transmit message buffer is empty, and thus not scheduled for transmission. The CPU must clear the flag after a message is set up in the transmit buffer and is due for transmission. The MSCAN sets the flag after the message is sent successfully. The flag is also set by the MSCAN when the transmission request is successfully aborted due to a pending abort request (see Section 8.3.2.9, “MSCAN Transmitter Message Abort Request Register (CANTARQ)”). If not masked, a transmit interrupt is pending while this flag is set. Clearing a TXEx flag also clears the corresponding ABTAKx (see Section 8.3.2.10, “MSCAN Transmitter Message Abort Acknowledge Register (CANTAAK)”)
When a TXEx flag is set, the corresponding ABTRQx bit is cleared (see Section 8.3.2.9, “MSCAN Transmitter Message Abort Request Register (CANTARQ)”).
When listen-mode is active (see Section 8.3.2.2, “MSCAN Control Register 1 (CANCTL1)”)
the TXEx flags cannot be cleared and no transmission is started.
Read and write accesses to the transmit buffer will be blocked, if the corresponding TXEx bit is cleared (TXEx = 0) and the buffer is scheduled for transmission.
0 The associated message buffer is full (loaded with a message due for transmission)
1 The associated message buffer is empty (not scheduled) |

8.3.2.8 MSCAN Transmitter Interrupt Enable Register (CANTIER)

This register contains the interrupt enable bits for the transmit buffer empty interrupt flags.
NOTE

The CANTIER register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Table 8-14. CANTIER Register Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 2-0       | TXEIE[2:0]  
0 No interrupt request is generated from this event.  
1 A transmitter empty (transmit buffer available for transmission) event causes a transmitter empty interrupt request. |

8.3.2.9 MSCAN Transmitter Message Abort Request Register (CANTARQ)

The CANTARQ register allows abort request of queued messages as described below.

![Figure 8-12. MSCAN Transmitter Message Abort Request Register (CANTARQ)]

NOTE

The CANTARQ register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Table 8-15. CANTARQ Register Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 2-0       | Abort Request — The CPU sets the ABTRQx bit to request that a scheduled message buffer (TXEx = 0) be aborted. The MSCAN grants the request if the message has not already started transmission, or if the transmission is not successful (lost arbitration or error). When a message is aborted, the associated TXE (see Section 8.3.2.7, “MSCAN Transmitter Flag Register (CANTFLG)” and abort acknowledge flags (ABTAK, see Section 8.3.2.10, “MSCAN Transmitter Message Abort Acknowledge Register (CANTAAK)” are set and a transmit interrupt occurs if enabled. The CPU cannot reset ABTRQx. ABTRQx is reset whenever the associated TXE flag is set.  
0 No abort request  
1 Abort request pending |
8.3.2.10 MSCAN Transmitter Message Abort Acknowledge Register (CANTAAK)

The CANTAAK register indicates the successful abort of a queued message, if requested by the appropriate bits in the CANTARQ register.

**NOTE**

The CANTAAK register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1).

![Figure 8-13. MSCAN Transmitter Message Abort Acknowledge Register (CANTAAK)](image)

**Table 8-16. CANTAAK Register Field Descriptions**

The ABTAKx flag is cleared whenever the corresponding TXE flag is cleared.</td>
</tr>
<tr>
<td>0</td>
<td>The message was not aborted.</td>
</tr>
<tr>
<td>1</td>
<td>The message was aborted.</td>
</tr>
</tbody>
</table>

8.3.2.11 MSCAN Transmit Buffer Selection Register (CANTBSEL)

The CANTBSEL register allows the selection of the actual transmit message buffer, which then will be accessible in the CANTXFG register space.

![Figure 8-14. MSCAN Transmit Buffer Selection Register (CANTBSEL)](image)

**Table 8-16. CANTAAK Register Field Descriptions**

1. Read: Find the lowest ordered bit set to 1, all other bits will be read as 0
   Write: Anytime when not in initialization mode
NOTE
The CANTBSEL register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK=1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

The following gives a short programming example of the usage of the CANTBSEL register:

To get the next available transmit buffer, application software must read the CANTFLG register and write this value back into the CANTBSEL register. In this example Tx buffers TX1 and TX2 are available. The value read from CANTFLG is therefore 0b0000_0110. When writing this value back to CANTBSEL, the Tx buffer TX1 is selected in the CANTXFG because the lowest numbered bit set to 1 is at bit position 1. Reading back this value out of CANTBSEL results in 0b0000_0010, because only the lowest numbered bit position set to 1 is presented. This mechanism eases the application software the selection of the next available Tx buffer.

- LDAA CANTFLG; value read is 0b0000_0110
- STAA CANTBSEL; value written is 0b0000_0110
- LDAA CANTBSEL; value read is 0b0000_0010

If all transmit message buffers are deselected, no accesses are allowed to the CANTXFG registers.

8.3.2.12 MSCAN Identifier Acceptance Control Register (CANIDAC)
The CANIDAC register is used for identifier acceptance control as described below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TX[2:0]</td>
<td>Transmit Buffer Select — The lowest numbered bit places the respective transmit buffer in the CANTXFG register space (e.g., TX1 = 1 and TX0 = 1 selects transmit buffer TX0; TX1 = 1 and TX0 = 0 selects transmit buffer TX1). Read and write accesses to the selected transmit buffer will be blocked, if the corresponding TXEx bit is cleared and the buffer is scheduled for transmission (see Section 8.3.2.7, “MSCAN Transmitter Flag Register (CANTFLG)&quot;).</td>
</tr>
<tr>
<td>0</td>
<td>The associated message buffer is deselected</td>
</tr>
<tr>
<td>1</td>
<td>The associated message buffer is selected, if lowest numbered bit</td>
</tr>
</tbody>
</table>

The following table gives a short programming example of the usage of the CANTBSEL register:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TX[2:0]</td>
<td>Transmit Buffer Select</td>
</tr>
<tr>
<td>0</td>
<td>The associated message buffer is deselected</td>
</tr>
<tr>
<td>1</td>
<td>The associated message buffer is selected, if lowest numbered bit</td>
</tr>
</tbody>
</table>

If all transmit message buffers are deselected, no accesses are allowed to the CANTXFG registers.

1. Read: Anytime
Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1), except bits IDHITx, which are read-only

Figure 8-15. MSCAN Identifier Acceptance Control Register (CANIDAC)
The IDHITx indicators are always related to the message in the foreground buffer (RxFG). When a message gets shifted into the foreground buffer of the receiver FIFO the indicators are updated as well.

### 8.3.2.13 MSCAN Reserved Register

This register is reserved for factory testing of the MSCAN module and is not available in normal system operating modes.

Reset: 00000000

= Unimplemented

NOTE

Reading this register when in any other mode other than sleep or initialization mode, may return an incorrect value. For MCUs with dual CPUs, this may result in a CPU fault condition.

Writing to this register when in special modes can alter the MSCAN functionality.
8.3.2.17  **MSCAN Identifier Acceptance Registers (CANIDAR0-7)**

On reception, each message is written into the background receive buffer. The CPU is only signalled to read the message if it passes the criteria in the identifier acceptance and identifier mask registers (accepted); otherwise, the message is overwritten by the next message (dropped).

The acceptance registers of the MSCAN are applied on the IDR0–IDR3 registers (see Section 8.3.3.1, “Identifier Registers (IDR0–IDR3)”) of incoming messages in a bit by bit manner (see Section 8.4.3, “Identifier Acceptance Filter”).

For extended identifiers, all four acceptance and mask registers are applied. For standard identifiers, only the first two (CANIDAR0/1, CANIDMR0/1) are applied.

![Figure 8-20. MSCAN Identifier Acceptance Registers (First Bank) — CANIDAR0–CANIDAR3](image)

1. Read: Anytime  
   Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1)

8.3.2.18 MSCAN Identifier Mask Registers (CANIDMR0–CANIDMR7)

The identifier mask register specifies which of the corresponding bits in the identifier acceptance register are relevant for acceptance filtering. To receive standard identifiers in 32 bit filter mode, it is required to program the last three bits (AM[2:0]) in the mask registers CANIDMR1 and CANIDMR5 to “don’t care.” To receive standard identifiers in 16 bit filter mode, it is required to program the last three bits (AM[2:0]) in the mask registers CANIDMR1, CANIDMR3, CANIDMR5, and CANIDMR7 to “don’t care.”

8.3.3  Programmer’s Model of Message Storage

The following section details the organization of the receive and transmit message buffers and the associated control registers.

To simplify the programmer interface, the receive and transmit message buffers have the same outline. Each message buffer allocates 16 bytes in the memory map containing a 13 byte data structure.

An additional transmit buffer priority register (TBPR) is defined for the transmit buffers. Within the last two bytes of this memory map, the MSCAN stores a special 16-bit time stamp, which is sampled from an internal timer after successful transmission or reception of a message. This feature is only available for transmit and receiver buffers, if the TIME bit is set (see Section 8.3.2.1, “MSCAN Control Register 0 (CANTL0)”).

The time stamp register is written by the MSCAN. The CPU can only read these registers.

1. Not applicable for receive buffers

Figure 8-24 shows the common 13-byte data structure of receive and transmit buffers for extended identifiers. The mapping of standard identifiers into the IDR registers is shown in Figure 8-25.

All bits of the receive and transmit buffers are ‘x’ out of reset because of RAM-based implementation. All reserved or unused bits of the receive and transmit buffers always read ‘x’.

8.3.3.4 Transmit Buffer Priority Register (TBPR)

This register defines the local priority of the associated message buffer. The local priority is used for the internal prioritization process of the MSCAN and is defined to be highest for the smallest binary number. The MSCAN implements the following internal prioritization mechanisms:

- All transmission buffers with a cleared TXEx flag participate in the prioritization immediately before the SOF (start of frame) is sent.
- The transmission buffer with the lowest local priority field wins the prioritization.
In cases of more than one buffer having the same lowest priority, the message buffer with the lower index number wins.

**Figure 8-36. Transmit Buffer Priority Register (TBPR)**

1. Read: Anytime when TXEx flag is set (see Section 8.3.2.7, “MSCAN Transmitter Flag Register (CANTFLG)”) and the corresponding transmit buffer is selected in CANTBSEL (see Section 8.3.2.11, “MSCAN Transmit Buffer Selection Register (CANTBSEL)”).
2. Write: Anytime when TXEx flag is set (see Section 8.3.2.7, “MSCAN Transmitter Flag Register (CANTFLG)”) and the corresponding transmit buffer is selected in CANTBSEL (see Section 8.3.2.11, “MSCAN Transmit Buffer Selection Register (CANTBSEL)”).

**8.3.3.5 Time Stamp Register (TSRH–TSRL)**

If the TIME bit is enabled, the MSCAN will write a time stamp to the respective registers in the active transmit or receive buffer right after the EOF of a valid message on the CAN bus (see Section 8.3.2.1, “MSCAN Control Register 0 (CANCTL0)”). In case of a transmission, the CPU can only read the time stamp after the respective transmit buffer has been flagged empty.

The timer value, which is used for stamping, is taken from a free running internal CAN bit clock. A timer overrun is not indicated by the MSCAN. The timer is reset (all bits set to 0) during initialization mode. The CPU can only read the time stamp registers.

**Figure 8-37. Time Stamp Register — High Byte (TSRH)**

1. Read: Anytime when TXEx flag is set (see Section 8.3.2.7, “MSCAN Transmitter Flag Register (CANTFLG)”) and the corresponding transmit buffer is selected in CANTBSEL (see Section 8.3.2.11, “MSCAN Transmit Buffer Selection Register (CANTBSEL)”).
2. Write: Unimplemented

**Figure 8-38. Time Stamp Register — Low Byte (TSRL)**
8.4 Functional Description

8.4.1 General

This section provides a complete functional description of the MSCAN.
8.4.2 Message Storage

The MSCAN facilitates a sophisticated message storage system which addresses the requirements of a broad range of network applications.

8.4.2.1 Message Transmit Background

Modern application layer software is built upon two fundamental assumptions:
Any CAN node is able to send out a stream of scheduled messages without releasing the CAN bus between the two messages. Such nodes arbitrate for the CAN bus immediately after sending the previous message and only release the CAN bus in case of lost arbitration.

The internal message queue within any CAN node is organized such that the highest priority message is sent out first, if more than one message is ready to be sent.

The behavior described in the bullets above cannot be achieved with a single transmit buffer. That buffer must be reloaded immediately after the previous message is sent. This loading process lasts a finite amount of time and must be completed within the inter-frame sequence (IFS) to be able to send an uninterrupted stream of messages. Even if this is feasible for limited CAN bus speeds, it requires that the CPU reacts with short latencies to the transmit interrupt.

A double buffer scheme de-couples the reloading of the transmit buffer from the actual message sending and, therefore, reduces the reactivity requirements of the CPU. Problems can arise if the sending of a message is finished while the CPU re-loads the second buffer. No buffer would then be ready for transmission, and the CAN bus would be released.

At least three transmit buffers are required to meet the first of the above requirements under all circumstances. The MSCAN has three transmit buffers.

The second requirement calls for some sort of internal prioritization which the MSCAN implements with the “local priority” concept described in Section 8.4.2.2, “Transmit Structures.”

### 8.4.2.2 Transmit Structures

The MSCAN triple transmit buffer scheme optimizes real-time performance by allowing multiple messages to be set up in advance. The three buffers are arranged as shown in Figure 8-39.

All three buffers have a 13-byte data structure similar to the outline of the receive buffers (see Section 8.3.3, “Programmer’s Model of Message Storage”). An additional Transmit Buffer Priority Register (TBPR) contains an 8-bit local priority field (PRIO) (see Section 8.3.3.4, “Transmit Buffer Priority Register (TBPR)”). The remaining two bytes are used for time stamping of a message, if required (see Section 8.3.3.5, “Time Stamp Register (TSRH–TSRL)

To transmit a message, the CPU must identify an available transmit buffer, which is indicated by a set transmitter buffer empty (TXEx) flag (see Section 8.3.2.7, “MSCAN Transmitter Flag Register (CANTFLG)

If a transmit buffer is available, the CPU must set a pointer to this buffer by writing to the CANTBSEL register (see Section 8.3.2.11, “MSCAN Transmit Buffer Selection Register (CANTBSEL)”). This makes the respective buffer accessible within the CANTXFG address space (see Section 8.3.3, “Programmer’s Model of Message Storage”). The algorithmic feature associated with the CANTBSEL register simplifies the transmit buffer selection. In addition, this scheme makes the handler software simpler because only one address area is applicable for the transmit process, and the required address space is minimized.

The CPU then stores the identifier, the control bits, and the data content into one of the transmit buffers. Finally, the buffer is flagged as ready for transmission by clearing the associated TXE flag.

---

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor

287
The MSCAN then schedules the message for transmission and signals the successful transmission of the buffer by setting the associated TXE flag. A transmit interrupt (see Section 8.4.7.2, “Transmit Interrupt”) is generated\(^1\) when TXEx is set and can be used to drive the application software to re-load the buffer.

If more than one buffer is scheduled for transmission when the CAN bus becomes available for arbitration, the MSCAN uses the local priority setting of the three buffers to determine the prioritization. For this purpose, every transmit buffer has an 8-bit local priority field (PRIO). The application software programs this field when the message is set up. The local priority reflects the priority of this particular message relative to the set of messages being transmitted from this node. The lowest binary value of the PRIO field is defined to be the highest priority. The internal scheduling process takes place whenever the MSCAN arbitrates for the CAN bus. This is also the case after the occurrence of a transmission error.

When a high priority message is scheduled by the application software, it may become necessary to abort a lower priority message in one of the three transmit buffers. Because messages that are already in transmission cannot be aborted, the user must request the abort by setting the corresponding abort request bit (ABTRQ) (see Section 8.3.2.9, “MSCAN Transmitter Message Abort Request Register (CANTARQ)”\(^{1}\)). The MSCAN then grants the request, if possible, by:

1. Setting the corresponding abort acknowledge flag (ABTAK) in the CANTAAK register.
2. Setting the associated TXE flag to release the buffer.
3. Generating a transmit interrupt. The transmit interrupt handler software can determine from the setting of the ABTAK flag whether the message was aborted (ABTAK = 1) or sent (ABTAK = 0).

### 8.4.2.3 Receive Structures

The received messages are stored in a five stage input FIFO. The five message buffers are alternately mapped into a single memory area (see Figure 8-39). The background receive buffer (RxBG) is exclusively associated with the MSCAN, but the foreground receive buffer (RxFG) is addressable by the CPU (see Figure 8-39). This scheme simplifies the handler software because only one address area is applicable for the receive process.

All receive buffers have a size of 15 bytes to store the CAN control bits, the identifier (standard or extended), the data contents, and a time stamp, if enabled (see Section 8.3.3, “Programmer’s Model of Message Storage”).

The receiver full flag (RXF) (see Section 8.3.2.5, “MSCAN Receiver Flag Register (CANRFLG)”) signals the status of the foreground receive buffer. When the buffer contains a correctly received message with a matching identifier, this flag is set.

On reception, each message is checked to see whether it passes the filter (see Section 8.4.3, “Identifier Acceptance Filter”) and simultaneously is written into the active RxBG. After successful reception of a valid message, the MSCAN shifts the content of RxBG into the receiver FIFO\(^2\), sets the RXF flag, and generates a receive interrupt (see Section 8.4.7.3, “Receive Interrupt”) to the CPU\(^3\). The user’s receive handler must read the received message from the RxFG and then reset the RXF flag to acknowledge the interrupt and to release the foreground buffer. A new message, which can follow immediately after the IFS field of the CAN frame, is received into the next available RxBG. If the MSCAN receives an invalid message, it only occurs if not masked. A polling scheme can be applied on TXEx also.

1. The transmit interrupt occurs only if not masked. A polling scheme can be applied on TXEx also.
2. Only if the RXF flag is not set.
3. The receive interrupt occurs only if not masked. A polling scheme can be applied on RXF also.
message in its RxBG (wrong identifier, transmission errors, etc.) the actual contents of the buffer will be over-written by the next message. The buffer will then not be shifted into the FIFO.

When the MSCAN module is transmitting, the MSCAN receives its own transmitted messages into the background receive buffer, RxBG, but does not shift it into the receiver FIFO, generate a receive interrupt, or acknowledge its own messages on the CAN bus. The exception to this rule is in loopback mode (see Section 8.3.2.2, “MSCAN Control Register 1 (CANCTL1)”) where the MSCAN treats its own messages exactly like all other incoming messages. The MSCAN receives its own transmitted messages in the event that it loses arbitration. If arbitration is lost, the MSCAN must be prepared to become a receiver.

An overrun condition occurs when all receive message buffers in the FIFO are filled with correctly received messages with accepted identifiers and another message is correctly received from the CAN bus with an accepted identifier. The latter message is discarded and an error interrupt with overrun indication is generated if enabled (see Section 8.4.7.5, “Error Interrupt”). The MSCAN remains able to transmit messages while the receiver FIFO being filled, but all incoming messages are discarded. As soon as a receive buffer in the FIFO is available again, new valid messages will be accepted.

8.4.3 Identifier Acceptance Filter

The MSCAN identifier acceptance registers (see Section 8.3.2.12, “MSCAN Identifier Acceptance Control Register (CANIDAC)”) define the acceptable patterns of the standard or extended identifier (ID[10:0] or ID[28:0]). Any of these bits can be marked ‘don’t care’ in the MSCAN identifier mask registers (see Section 8.3.2.18, “MSCAN Identifier Mask Registers (CANIDMR0–CANIDMR7)”).

A filter hit is indicated to the application software by a set receive buffer full flag (RXF = 1) and three bits in the CANIDAC register (see Section 8.3.2.12, “MSCAN Identifier Acceptance Control Register (CANIDAC)”). These identifier hit flags (IDHIT[2:0]) clearly identify the filter section that caused the acceptance. They simplify the application software’s task to identify the cause of the receiver interrupt. If more than one hit occurs (two or more filters match), the lower hit has priority.

A very flexible programmable generic identifier acceptance filter has been introduced to reduce the CPU interrupt loading. The filter is programmable to operate in four different modes (see Bosch CAN 2.0A/B protocol specification):

- Two identifier acceptance filters, each to be applied to:
  - The full 29 bits of the extended identifier and to the following bits of the CAN 2.0B frame:
    - Remote transmission request (RTR)
    - Identifier extension (IDE)
    - Substitute remote request (SRR)
  - The 11 bits of the standard identifier plus the RTR and IDE bits of the CAN 2.0A/B messages. This mode implements two filters for a full length CAN 2.0B compliant extended identifier. Figure 8-40 shows how the first 32-bit filter bank (CANidar0–CANidar3, CANIDMR0–CANIDMR3) produces a filter 0 hit. Similarly, the second filter bank (CANidar4–CANidar7, CANIDMR4–CANIDMR7) produces a filter 1 hit.

- Four identifier acceptance filters, each to be applied to

1. Although this mode can be used for standard identifiers, it is recommended to use the four or eight identifier acceptance filters for standard identifiers.
— a) the 14 most significant bits of the extended identifier plus the SRR and IDE bits of CAN 2.0B messages or
— b) the 11 bits of the standard identifier, the RTR and IDE bits of CAN 2.0A/B messages. Figure 8-41 shows how the first 32-bit filter bank (CANIDAR0–CANIDA3, CANIDMR0–3CANIDMR) produces filter 0 and 1 hits. Similarly, the second filter bank (CANIDAR4–CANIDAR7, CANIDMR4–CANIDMR7) produces filter 2 and 3 hits.

- Eight identifier acceptance filters, each to be applied to the first 8 bits of the identifier. This mode implements eight independent filters for the first 8 bits of a CAN 2.0A/B compliant standard identifier or a CAN 2.0B compliant extended identifier. Figure 8-42 shows how the first 32-bit filter bank (CANIDAR0–CANIDAR3, CANIDMR0–CANIDMR3) produces filter 0 to 3 hits. Similarly, the second filter bank (CANIDAR4–CANIDAR7, CANIDMR4–CANIDMR7) produces filter 4 to 7 hits.
- Closed filter. No CAN message is copied into the foreground buffer RxFG, and the RXF flag is never set.

![Figure 8-40. 32-bit Maskable Identifier Acceptance Filter](image-url)
Figure 8-41. 16-bit Maskable Identifier Acceptance Filters
Figure 8-42. 8-bit Maskable Identifier Acceptance Filters
8.4.3.1 Protocol Violation Protection

The MSCAN protects the user from accidentally violating the CAN protocol through programming errors. The protection logic implements the following features:

- The receive and transmit error counters cannot be written or otherwise manipulated.
- All registers which control the configuration of the MSCAN cannot be modified while the MSCAN is on-line. The MSCAN has to be in Initialization Mode. The corresponding INITRQ/INITAK handshake bits in the CANCTL0/CANCTL1 registers (see Section 8.3.2.1, “MSCAN Control Register 0 (CANCTL0)”) serve as a lock to protect the following registers:
  - MSCAN control 1 register (CANCTL1)
  - MSCAN bus timing registers 0 and 1 (CANBTR0, CANBTR1)
  - MSCAN identifier acceptance control register (CANIDAC)
  - MSCAN identifier acceptance registers (CANIDAR0–CANIDAR7)
  - MSCAN identifier mask registers (CANIDMR0–CANIDMR7)
- The TXCAN is immediately forced to a recessive state when the MSCAN goes into the power down mode or initialization mode (see Section 8.4.5.6, “MSCAN Power Down Mode,” and Section 8.4.4.5, “MSCAN Initialization Mode”).
- The MSCAN enable bit (CANE) is writable only once in normal system operation modes, which provides further protection against inadvertently disabling the MSCAN.

8.4.3.2 Clock System

Figure 8-43 shows the structure of the MSCAN clock generation circuitry.

The clock source bit (CLKSRC) in the CANCTL1 register (8.3.2.2/8-259) defines whether the internal CANCLK is connected to the output of a crystal oscillator (oscillator clock) or to the bus clock.

The clock source has to be chosen such that the tight oscillator tolerance requirements (up to 0.4%) of the CAN protocol are met. Additionally, for high CAN bus rates (1 Mbps), a 45% to 55% duty cycle of the clock is required.

If the bus clock is generated from a PLL, it is recommended to select the oscillator clock rather than the bus clock due to jitter considerations, especially at the faster CAN bus rates.
For microcontrollers without a clock and reset generator (C3RG), CANCLK is driven from the crystal oscillator (oscillator clock).

A programmable prescaler generates the time quanta (Tq) clock from CANCLK. A time quantum is the atomic unit of time handled by the MSCAN.

\[
Tq = \frac{f_{CANCLK}}{(\text{Prescaler value})}
\]

A bit time is subdivided into three segments as described in the Bosch CAN specification. (see Figure 8-44):

- **SYNC_SEG**: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- **Time Segment 1**: This segment includes the PROP_SEG and the PHASE_SEG1 of the CAN standard. It can be programmed by setting the parameter TSEG1 to consist of 4 to 16 time quanta.
- **Time Segment 2**: This segment represents the PHASE_SEG2 of the CAN standard. It can be programmed by setting the TSEG2 parameter to be 2 to 8 time quanta long.

\[
\text{Bit Rate} = \frac{f_{Tq}}{(\text{number of Time Quanta})}
\]

**Figure 8-44. Segments within the Bit Time**
The synchronization jump width (see the Bosch CAN specification for details) can be programmed in a range of 1 to 4 time quanta by setting the SJW parameter.

The SYNC_SEG, TSEG1, TSEG2, and SJW parameters are set by programming the MSCAN bus timing registers (CANBTR0, CANBTR1) (see Section 8.3.2.3, “MSCAN Bus Timing Register 0 (CANBTR0)” and Section 8.3.2.4, “MSCAN Bus Timing Register 1 (CANBTR1)”).

Table 8-37 gives an overview of the CAN compliant segment settings and the related parameter values.

**NOTE**

It is the user’s responsibility to ensure the bit time settings are in compliance with the CAN standard.

### 8.4.4 Modes of Operation

#### 8.4.4.1 Normal System Operating Modes

The MSCAN module behaves as described within this specification in all normal system operating modes. Write restrictions exist for some registers.
8.4.4.2 Special System Operating Modes
The MSCAN module behaves as described within this specification in all special system operating modes. Write restrictions which exist on specific registers in normal modes are lifted for test purposes in special modes.

8.4.4.3 Emulation Modes
In all emulation modes, the MSCAN module behaves just like in normal system operating modes as described within this specification.

8.4.4.4 Listen-Only Mode
In an optional CAN bus monitoring mode (listen-only), the CAN node is able to receive valid data frames and valid remote frames, but it sends only “recessive” bits on the CAN bus. In addition, it cannot start a transmission.

If the MAC sub-layer is required to send a “dominant” bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the MAC sub-layer monitors this “dominant” bit, although the CAN bus may remain in recessive state externally.

8.4.4.5 MSCAN Initialization Mode
The MSCAN enters initialization mode when it is enabled (CANE=1).

When entering initialization mode during operation, any on-going transmission or reception is immediately aborted and synchronization to the CAN bus is lost, potentially causing CAN protocol violations. To protect the CAN bus system from fatal consequences of violations, the MSCAN immediately drives TXCAN into a recessive state.

NOTE
The user is responsible for ensuring that the MSCAN is not active when initialization mode is entered. The recommended procedure is to bring the MSCAN into sleep mode (SLPRQ = 1 and SLPAK = 1) before setting the INITRQ bit in the CANCTL0 register. Otherwise, the abort of an on-going message can cause an error condition and can impact other CAN bus devices.

In initialization mode, the MSCAN is stopped. However, interface registers remain accessible. This mode is used to reset the CANCTL0, CANRFLG, CANRIER, CANTFLG, CANTIER, CANTARQ, CANTAAK, and CANTBSEL registers to their default values. In addition, the MSCAN enables the configuration of the CANBTR0, CANBTR1 bit timing registers; CANIDAC; and the CANIDAR, CANIDMR message filters. See Section 8.3.2.1, “MSCAN Control Register 0 (CANCTL0),” for a detailed description of the initialization mode.
Due to independent clock domains within the MSCAN, INITRQ must be synchronized to all domains by using a special handshake mechanism. This handshake causes additional synchronization delay (see Section Figure 8-45, “Initialization Request/Acknowledge Cycle”).

If there is no message transfer ongoing on the CAN bus, the minimum delay will be two additional bus clocks and three additional CAN clocks. When all parts of the MSCAN are in initialization mode, the INITAK flag is set. The application software must use INITAK as a handshake indication for the request (INITRQ) to go into initialization mode.

**NOTE**

The CPU cannot clear INITRQ before initialization mode (INITRQ = 1 and INITAK = 1) is active.

### 8.4.5 Low-Power Options

If the MSCAN is disabled (CANE = 0), the MSCAN clocks are stopped for power saving.

If the MSCAN is enabled (CANE = 1), the MSCAN has two additional modes with reduced power consumption, compared to normal mode: sleep and power down mode. In sleep mode, power consumption is reduced by stopping all clocks except those to access the registers from the CPU side. In power down mode, all clocks are stopped and no power is consumed.

Table 8-38 summarizes the combinations of MSCAN and CPU modes. A particular combination of modes is entered by the given settings on the CSWAI and SLPRQ/SLPAK bits.
8.4.5.1 Operation in Run Mode

As shown in Table 8-38, only MSCAN sleep mode is available as low power option when the CPU is in run mode.

8.4.5.2 Operation in Wait Mode

The WAI instruction puts the MCU in a low power consumption stand-by mode. If the CSWAI bit is set, additional power can be saved in power down mode because the CPU clocks are stopped. After leaving this power down mode, the MSCAN restarts and enters normal mode again.

While the CPU is in wait mode, the MSCAN can be operated in normal mode and generate interrupts (registers can be accessed via background debug mode).

8.4.5.3 Operation in Stop Mode

The STOP instruction puts the MCU in a low power consumption stand-by mode. In stop mode, the MSCAN is set in power down mode regardless of the value of the SLPRQ/SLPAK and CSWAI bits (Table 8-38).

8.4.5.4 MSCAN Normal Mode

This is a non-power-saving mode. Enabling the MSCAN puts the module from disabled mode into normal mode. In this mode the module can either be in initialization mode or out of initialization mode. See Section 8.4.4.5, “MSCAN Initialization Mode”.

</tr>
</tbody>
</table>

1. 'X' means don’t care.

Table 8-38. CPU vs. MSCAN Operating Modes
### 8.4.5.5 MSCAN Sleep Mode

The CPU can request the MSCAN to enter this low power mode by asserting the SLPRQ bit in the CANCTL0 register. The time when the MSCAN enters sleep mode depends on a fixed synchronization delay and its current activity:

- If there are one or more message buffers scheduled for transmission (TXEx = 0), the MSCAN will continue to transmit until all transmit message buffers are empty (TXEx = 1, transmitted successfully or aborted) and then goes into sleep mode.
- If the MSCAN is receiving, it continues to receive and goes into sleep mode as soon as the CAN bus next becomes idle.
- If the MSCAN is neither transmitting nor receiving, it immediately goes into sleep mode.

![Sleep Request / Acknowledge Cycle](image)

**Figure 8-46. Sleep Request / Acknowledge Cycle**

**NOTE**

The application software must avoid setting up a transmission (by clearing one or more TXEx flag(s)) and immediately request sleep mode (by setting SLPRQ). Whether the MSCAN starts transmitting or goes into sleep mode directly depends on the exact sequence of operations.

If sleep mode is active, the SLPRQ and SLPAK bits are set (Figure 8-46). The application software must use SLPAK as a handshake indication for the request (SLPRQ) to go into sleep mode.

When in sleep mode (SLPRQ = 1 and SLPAK = 1), the MSCAN stops its internal clocks. However, clocks that allow register accesses from the CPU side continue to run.

If the MSCAN is in bus-off state, it stops counting the 128 occurrences of 11 consecutive recessive bits due to the stopped clocks. TXCAN remains in a recessive state. If RXF = 1, the message can be read and RXF can be cleared. Shifting a new message into the foreground buffer of the receiver FIFO (RxFG) does not take place while in sleep mode.

It is possible to access the transmit buffers and to clear the associated TXE flags. No message abort takes place while in sleep mode.
If the WUPE bit in CANCTL0 is not asserted, the MSCAN will mask any activity it detects on CAN. RXCAN is therefore held internally in a recessive state. This locks the MSCAN in sleep mode. WUPE must be set before entering sleep mode to take effect.

The MSCAN is able to leave sleep mode (wake up) only when:

- CAN bus activity occurs and WUPE = 1
- the CPU clears the SLPRQ bit

**NOTE**

The CPU cannot clear the SLPRQ bit before sleep mode (SLPRQ = 1 and SLPAK = 1) is active.

After wake-up, the MSCAN waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, if the MSCAN is woken-up by a CAN frame, this frame is not received.

The receive message buffers (RxFG and RxBG) contain messages if they were received before sleep mode was entered. All pending actions will be executed upon wake-up; copying of RxBG into RxFG, message aborts and message transmissions. If the MSCAN remains in bus-off state after sleep mode was exited, it continues counting the 128 occurrences of 11 consecutive recessive bits.

### 8.4.5.6 MSCAN Power Down Mode

The MSCAN is in power down mode (Table 8-38) when

- CPU is in stop mode
- CPU is in wait mode and the CSWAI bit is set

When entering the power down mode, the MSCAN immediately stops all ongoing transmissions and receptions, potentially causing CAN protocol violations. To protect the CAN bus system from fatal consequences of violations to the above rule, the MSCAN immediately drives TXCAN into a recessive state.

**NOTE**

The user is responsible for ensuring that the MSCAN is not active when power down mode is entered. The recommended procedure is to bring the MSCAN into Sleep mode before the STOP or WAI instruction (if CSWAI is set) is executed. Otherwise, the abort of an ongoing message can cause an error condition and impact other CAN bus devices.

In power down mode, all clocks are stopped and no registers can be accessed. If the MSCAN was not in sleep mode before power down mode became active, the module performs an internal recovery cycle after powering up. This causes some fixed delay before the module enters normal mode again.
8.4.5.7 Disabled Mode

The MSCAN is in disabled mode out of reset (CANE=0). All module clocks are stopped for power saving, however the register map can still be accessed as specified.

8.4.5.8 Programmable Wake-Up Function

The MSCAN can be programmed to wake up from sleep or power down mode as soon as CAN bus activity is detected (see control bit WUPE in MSCAN Control Register 0 (CANCTL0). The sensitivity to existing CAN bus action can be modified by applying a low-pass filter function to the RXCAN input line (see control bit WUPM in Section 8.3.2.2, “MSCAN Control Register 1 (CANCTL1)”).

This feature can be used to protect the MSCAN from wake-up due to short glitches on the CAN bus lines. Such glitches can result from—for example—electromagnetic interference within noisy environments.

8.4.6 Reset Initialization

The reset state of each individual bit is listed in Section 8.3.2, “Register Descriptions,” which details all the registers and their bit-fields.

8.4.7 Interrupts

This section describes all interrupts originated by the MSCAN. It documents the enable bits and generated flags. Each interrupt is listed and described separately.

8.4.7.1 Description of Interrupt Operation

The MSCAN supports four interrupt vectors (see Table 8-39), any of which can be individually masked (for details see Section 8.3.2.6, “MSCAN Receiver Interrupt Enable Register (CANRIER)” to Section 8.3.2.8, “MSCAN Transmitter Interrupt Enable Register (CANTIER)”).

NOTE

The dedicated interrupt vector addresses are defined in the Resets and Interrupts chapter.

Table 8-39. Interrupt Vectors

<table>
<thead>
<tr>
<th>Interrupt Source</th>

<td>CANRIER (RXFIE)</td>
</tr>
<tr>
<td>Transmit Interrupts (TXE[2:0])</td>
<td>I bit</td>
<td>CANTIER (TXEIE[2:0])</td>
</tr>
</tbody>
</table>

8.4.7.2 Transmit Interrupt

At least one of the three transmit buffers is empty (not scheduled) and can be loaded to schedule a message for transmission. The TXEx flag of the empty message buffer is set.
8.4.7.3 Receive Interrupt

A message is successfully received and shifted into the foreground buffer (RxFG) of the receiver FIFO. This interrupt is generated immediately after receiving the EOF symbol. The RXF flag is set. If there are multiple messages in the receiver FIFO, the RXF flag is set as soon as the next message is shifted to the foreground buffer.

8.4.7.4 Wake-Up Interrupt

A wake-up interrupt is generated if activity on the CAN bus occurs during MSCAN sleep or power-down mode.

NOTE

This interrupt can only occur if the MSCAN was in sleep mode (SLPRQ = 1 and SLPACK = 1) before entering power down mode, the wake-up option is enabled (WUPE = 1), and the wake-up interrupt is enabled (WUPIE = 1).

8.4.7.5 Error Interrupt

An error interrupt is generated if an overrun of the receiver FIFO, error, warning, or bus-off condition occurs. MSCAN Receiver Flag Register (CANRFLG) indicates one of the following conditions:

- **Overrun** — An overrun condition of the receiver FIFO as described in Section 8.4.2.3, “Receive Structures,” occurred.

- **CAN Status Change** — The actual value of the transmit and receive error counters control the CAN bus state of the MSCAN. As soon as the error counters skip into a critical range (Tx/Rx-warning, Tx/Rx-error, bus-off) the MSCAN flags an error condition. The status change, which caused the error condition, is indicated by the TSTAT and RSTAT flags (see Section 8.3.2.5, “MSCAN Receiver Flag Register (CANRFLG)” and Section 8.3.2.6, “MSCAN Receiver Interrupt Enable Register (CANRIER)”).

8.4.7.6 Interrupt Acknowledge

Interrupts are directly associated with one or more status flags in either the MSCAN Receiver Flag Register (CANRFLG) or the MSCAN Transmitter Flag Register (CANTFLG). Interrupts are pending as long as one of the corresponding flags is set. The flags in CANRFLG and CANTFLG must be reset within the interrupt handler to handshake the interrupt. The flags are reset by writing a 1 to the corresponding bit position. A flag cannot be cleared if the respective condition prevails.

NOTE

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.
8.5 Initialization/Application Information

8.5.1 MSCAN initialization

The procedure to initially start up the MSCAN module out of reset is as follows:

1. Assert CANE
2. Write to the configuration registers in initialization mode
3. Clear INITRQ to leave initialization mode

If the configuration of registers which are only writable in initialization mode shall be changed:

1. Bring the module into sleep mode by setting SLPRQ and awaiting SLPAK to assert after the CAN bus becomes idle.
2. Enter initialization mode: assert INITRQ and await INITAK
3. Write to the configuration registers in initialization mode
4. Clear INITRQ to leave initialization mode and continue

8.5.2 Bus-Off Recovery

The bus-off recovery is user configurable. The bus-off state can either be left automatically or on user request.

For reasons of backwards compatibility, the MSCAN defaults to automatic recovery after reset. In this case, the MSCAN will become error active again after counting 128 occurrences of 11 consecutive recessive bits on the CAN bus (see the Bosch CAN specification for details).

If the MSCAN is configured for user request (BORM set in MSCAN Control Register 1 (CANCTL1)), the recovery from bus-off starts after both independent events have become true:

- 128 occurrences of 11 consecutive recessive bits on the CAN bus have been monitored
- BOHOLD in MSCAN Miscellaneous Register (CANMISC) has been cleared by the user

These two events may occur in any order.

9.1 Introduction

The ADC12B10C is a 10-channel, 12-bit, multiplexed input successive approximation analog-to-digital converter. Refer to device electrical specifications for ATD accuracy.

9.1.1 Features

- 8-, 10-, or 12-bit resolution.
- Conversion in Stop Mode using internally generated clock
- Automatic return to low power after conversion sequence
- Automatic compare with interrupt for higher than or less/equal than programmable value
- Programmable sample time.
- Left/right justified result data.
- External trigger control.
- Sequence complete interrupt.
- Analog input multiplexer for 10 analog input channels.
- Special conversions for $V_{RH}$, $V_{RL}$, $(V_{RL}+V_{RH})/2$.
- 1-to-10 conversion sequence lengths.
- Continuous conversion mode.
- Multiple channel scans.
• Configurable external trigger functionality on any AD channel or any of four additional trigger inputs. The four additional trigger inputs can be chip external or internal. Refer to device specification for availability and connectivity.
• Configurable location for channel wrap around (when converting multiple channels in a sequence).

9.1.2 Modes of Operation

9.1.2.1 Conversion Modes
There is software programmable selection between performing single or continuous conversion on a single channel or multiple channels.

9.1.2.2 MCU Operating Modes

• Stop Mode
  — I CLKSTP=0 (in ATDCTL2 register)
    Entering Stop Mode aborts any conversion sequence in progress and if a sequence was aborted restarts it after exiting stop mode. This has the same effect/consequences as starting a conversion sequence with write to ATDCTL5. So after exiting from stop mode with a previously aborted sequence all flags are cleared etc.
  — I CLKSTP=1 (in ATDCTL2 register)
    A/D conversion sequence seamless continues in Stop Mode based on the internally generated clock ICLK as ATD clock. For conversions during transition from Run to Stop Mode or vice versa the result is not written to the results register, no CCF flag is set and no compare is done. When converting in Stop Mode (ICLKSTP=1) an ATD Stop Recovery time $t_{ATDSTPRCV}$ is required to switch back to bus clock based ATDCLK when leaving Stop Mode. Do not access ATD registers during this time.

• Wait Mode
  ADC12B10C behaves same in Run and Wait Mode. For reduced power consumption continuous conversions should be aborted before entering Wait mode.

• Freeze Mode
  In Freeze Mode the ADC12B10C will either continue or finish or stop converting according to the FRZ1 and FRZ0 bits. This is useful for debugging and emulation.
9.1.3 Block Diagram

Figure 9-1. ADC12B10C Block Diagram
9.2 Signal Description
This section lists all inputs to the ADC12B10C block.

9.2.1 Detailed Signal Descriptions

9.2.1.1 ANx (x = 9, 8, 7, 6, 5, 4, 3, 2, 1, 0)
This pin serves as the analog input Channel x. It can also be configured as digital port or external trigger for the ATD conversion.

9.2.1.2 ETRIG3, ETRIG2, ETRIG1, ETRIG0
These inputs can be configured to serve as an external trigger for the ATD conversion. Refer to device specification for availability and connection of these inputs!

9.2.1.3 V_{RH}, V_{RL}
V_{RH} is the high reference voltage, V_{RL} is the low reference voltage for ATD conversion.

9.2.1.4 V_{DDA}, V_{SSA}
These pins are the power supplies for the analog circuitry of the ADC12B10C block.

9.3 Memory Map and Register Definition
This section provides a detailed description of all registers accessible in the ADC12B10C.

9.3.1 Module Memory Map
Figure 9-2 gives an overview on all ADC12B10C registers.

\[

<td>ICLKSTP</td>
</tr>
<tr>
<td>0</td>
<td>Internal Clock in Stop Mode Bit — This bit enables A/D conversions in stop mode. When going into stop mode and ICLKSTP=1 the ATD conversion clock is automatically switched to the internally generated clock ICLK. Current conversion sequence will seamlessly continue. Conversion speed will change from prescaled bus frequency to the ICLK frequency (see ATD Electrical Characteristics in device description). The prescaler bits PRS4-0 in ATDCTL4 have no effect on the ICLK frequency. For conversions during stop mode the automatic compare interrupt or the sequence complete interrupt can be used to inform software handler about changing A/D values. External trigger will not work while converting in stop mode. For conversions during transition from Run to Stop Mode or vice versa the result is not written to the results register, no CCF flag is set and no compare is done. When converting in Stop Mode (ICLKSTP=1) an ATD Stop Recovery time t\textsubscript{ATDSTPRCV} is required to switch back to bus clock based ATDCLK when leaving Stop Mode. Do not access ATD registers during this time.</td>

### Table 9-8. ATDCTL3 Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 DJM | **Result Register Data Justification** — Result data format is always unsigned. This bit controls justification of conversion data in the result registers.  
0 Left justified data in the result registers.  
1 Right justified data in the result registers.  
Table 9-9 gives examples ATD results for an input signal range between 0 and 5.12 Volts. |
| 6-3 S8C, S4C, S2C, S1C | **Conversion Sequence Length** — These bits control the number of conversions per sequence. Table 9-10 shows all combinations. At reset, S4C is set to 1 (sequence length is 4). This is to maintain software continuity to HC12 family. |
| 2 FIFO | **Result Register FIFO Mode** — If this bit is zero (non-FIFO mode), the A/D conversion results map into the result registers based on the conversion sequence; the result of the first conversion appears in the first result register (ATDDR0), the second result in the second result register (ATDDR1), and so on.  
If this bit is one (FIFO mode) the conversion counter is not reset at the beginning or ending of a conversion sequence; sequential conversion results are placed in consecutive result registers. In a continuously scanning conversion sequence, the result register counter will wrap around when it reaches the end of the result register file. The conversion counter value (CC3-0 in ATDSTAT0) can be used to determine where in the result register file, the current conversion result will be placed.  
Aborting a conversion or starting a new conversion clears the conversion counter even if FIFO=1. So the first result of a new conversion sequence, started by writing to ATDCTL5, will always be place in the first result register (ATDDDR0). Intended usage of FIFO mode is continuos conversion (SCAN=1) or triggered conversion (ETRIG=1).  
Which result registers hold valid data can be tracked using the conversion complete flags. Fast flag clear mode may or may not be useful in a particular application to track valid data.  
If this bit is one, automatic compare of result registers is always disabled, that is ADC12B10C will behave as if ACMPIE and all CPME[n] were zero.  
0 Conversion results are placed in the corresponding result register up to the selected sequence length.  
1 Conversion results are placed in consecutive result registers (wrap around at end). |
| 1–0 FRZ[1:0] | **Background Debug Freeze Enable** — When debugging an application, it is useful in many cases to have the ATD pause when a breakpoint (Freeze Mode) is encountered. These 2 bits determine how the ATD will respond to a breakpoint as shown in Table 9-11. Leakage onto the storage node and comparator reference capacitors may compromise the accuracy of an immediately frozen conversion depending on the length of the freeze period. |

9.3.2.6 ATD Control Register 5 (ATDCTL5)

Writes to this register will abort current conversion sequence and start a new conversion sequence. If external trigger is enabled (ETRIGE=1) an initial write to ATDCTL5 is required to allow starting of a conversion sequence which will then occur on each trigger event. Start of conversion means the beginning of the sampling phase.

### Table 9-16. ATDSTAT0 Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 SCF | **Sequence Complete Flag** — This flag is set upon completion of a conversion sequence. If conversion sequences are continuously performed (SCAN=1), the flag is set after each one is completed. This flag is cleared when one of the following occurs:  
  A) Write “1” to SCF  
  B) Write to ATDCTL5 (a new conversion sequence is started)  
  C) If AFFC=1 and read of a result register  
  0 Conversion sequence not completed  
  1 Conversion sequence has completed |
| 5 ETORF | **External Trigger Overrun Flag** — While in edge trigger mode (ETRIGLE=0), if additional active edges are detected while a conversion sequence is in process the overrun flag is set. This flag is cleared when one of the following occurs:  
  A) Write “1” to ETORF  
  B) Write to ATDCTL0,1,2,3,4, ATDCMPE or ATDCMPHT (a conversion sequence is aborted)  
  C) Write to ATDCTL5 (a new conversion sequence is started)  
  0 No External trigger over run error has occurred  
  1 External trigger over run error has occurred |
| 4 FIFOR | **Result Register Over Run Flag** — This bit indicates that a result register has been written to before its associated conversion complete flag (CCF) has been cleared. This flag is most useful when using the FIFO mode because the flag potentially indicates that result registers are out of sync with the input channels. However, it is also practical for non-FIFO modes, and indicates that a result register has been over written before it has been read (i.e. the old data has been lost). This flag is cleared when one of the following occurs:  
  A) Write “1” to FIFOR  
  B) Write to ATDCTL0,1,2,3,4, ATDCMPE or ATDCMPHT (a conversion sequence is aborted)  
  C) Write to ATDCTL5 (a new conversion sequence is started)  
  0 No over run has occurred  
  1 Overrun condition exists (result register has been written while associated CCFx flag was still set) |
| 3–0 CC[3:0] | **Conversion Counter** — These 4 read-only bits are the binary value of the conversion counter. The conversion counter points to the result register that will receive the result of the current conversion. E.g. CC3=0, CC2=1, CC1=1, CC0=0 indicates that the result of the current conversion will be in ATD Result Register 6. If in non-FIFO mode (FIFO=0) the conversion counter is initialized to zero at the begin and end of the conversion sequence. If in FIFO mode (FIFO=1) the register counter is not initialized. The conversion counters wraps around when its maximum value is reached.  
  Aborting a conversion or starting a new conversion clears the conversion counter even if FIFO=1.

0 If result of conversion $n$ is lower or same than compare value in ATDDR$n$, this is flagged in ATDSTAT2
1 If result of conversion $n$ is higher than compare value in ATDDR$n$, this is flagged in ATDSTAT2 |

Figure 9-13. ATD Compare Higher Than Register (ATDCMPHT)

Table 9-20. ATDCMPHT Field Descriptions

9.3.2.12 ATD Conversion Result Registers (ATDDR$n$)

The A/D conversion results are stored in 10 result registers. Results are always in unsigned data representation. Left and right justification is selected using the DJM control bit in ATDCTL3.

If automatic compare of conversions results is enabled (CMPE[$n$]=1 in ATDCMPE), these registers must be written with the compare values in left or right justified format depending on the actual value of the DJM bit. In this case, as the ATDDR$n$ register is used to hold the compare value, the result will not be stored there at the end of the conversion but is lost.

Attention, $n$ is the conversion number, NOT the channel number!

Read: Anytime
Write: Anytime

NOTE

For conversions not using automatic compare, results are stored in the result registers after each conversion. In this case avoid writing to ATDDR$n$ except for initial values, because an A/D result might be overwritten.

9.4 Functional Description

The ADC12B10C is structured into an analog sub-block and a digital sub-block.
9.4.1 Analog Sub-Block

The analog sub-block contains all analog electronics required to perform a single conversion. Separate power supplies $V_{DDA}$ and $V_{SSA}$ allow to isolate noise of other MCU circuitry from the analog sub-block.

9.4.1.1 Sample and Hold Machine

The Sample and Hold (S/H) Machine accepts analog signals from the external world and stores them as capacitor charge on a storage node.

During the sample process the analog input connects directly to the storage node.

The input analog signals are unipolar and must fall within the potential range of $V_{SSA}$ to $V_{DDA}$.

During the hold process the analog input is disconnected from the storage node.

9.4.1.2 Analog Input Multiplexer

The analog input multiplexer connects one of the 10 external analog input channels to the sample and hold machine.

9.4.1.3 Analog-to-Digital (A/D) Machine

The A/D Machine performs analog to digital conversions. The resolution is program selectable at either 8 or 10 or 12 bits. The A/D machine uses a successive approximation architecture. It functions by comparing the stored analog sample potential with a series of digitally generated analog potentials. By following a binary search algorithm, the A/D machine locates the approximating potential that is nearest to the sampled potential.

When not converting the A/D machine is automatically powered down.

Only analog input signals within the potential range of $V_{RL}$ to $V_{RH}$ (A/D reference potentials) will result in a non-railed digital output code.

9.4.2 Digital Sub-Block

This subsection explains some of the digital features in more detail. See Section 9.3.2, “Register Descriptions” for all details.

9.4.2.1 External Trigger Input

The external trigger feature allows the user to synchronize ATD conversions to the external environment events rather than relying on software to signal the ATD module when ATD conversions are to take place. The external trigger signal (out of reset ATD channel 9, configurable in ATDCTL1) is programmable to
be edge or level sensitive with polarity control. Table 9-22 gives a brief description of the different combinations of control bits and their effect on the external trigger function.

### Table 9-22. External Trigger Control Bits

</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>X</td>
<td>Trigger active high. Performs continuous conversions while trigger is active.</td>
</tr>
</tbody>
</table>

During a conversion, if additional active edges are detected the overrun error flag ETORF is set.

In either level or edge triggered modes, the first conversion begins when the trigger is received. Once ETRIGE is enabled, conversions cannot be started by a write to ATDCTL5, but rather must be triggered externally.

If the level mode is active and the external trigger both de-asserts and re-asserts itself during a conversion sequence, this does not constitute an overrun. Therefore, the flag is not set. If the trigger is left asserted in level mode while a sequence is completing, another sequence will be triggered immediately.

### 9.4.2.2 General-Purpose Digital Port Operation

The input channel pins can be multiplexed between analog and digital data. As analog inputs, they are multiplexed and sampled as analog channels to the A/D converter. The analog/digital multiplex operation is performed in the input pads. The input pad is always connected to the analog input channels of the ADC12B10C. The input pad signal is buffered to the digital port registers. This buffer can be turned on or off with the ATDDIEN register. This is important so that the buffer does not draw excess current when analog potentials are presented at its input.

### 9.5 Resets

At reset the ADC12B10C is in a power down state. The reset state of each individual bit is listed within the Register Description section (see Section 9.3.2, “Register Descriptions”) which details the registers and their bit-field.
9.6 **Interrupts**

The interrupts requested by the ADC12B10C are listed in Table 9-23. Refer to MCU specification for related vector address and priority.

See Section 9.3.2, “Register Descriptions” for further details.
Chapter 10
Pulse-Width Modulator (PWM8B6CV1) Block Description

10.1 Introduction

The pulse width modulation (PWM) definition is based on the HC12 PWM definitions. The PWM8B6CV1 module contains the basic features from the HC11 with some of the enhancements incorporated on the HC12, that is center aligned output mode and four available clock sources. The PWM8B6CV1 module has six channels with independent control of left and center aligned outputs on each channel.

Each of the six PWM channels has a programmable period and duty cycle as well as a dedicated counter. A flexible clock select scheme allows a total of four different clock sources to be used with the counters. Each of the modulators can create independent continuous waveforms with software-selectable duty rates from 0% to 100%. The PWM outputs can be programmed as left aligned outputs or center aligned outputs.

10.1.1 Features

- Six independent PWM channels with programmable period and duty cycle
- Dedicated counter for each PWM channel
- Programmable PWM enable/disable for each channel
- Software selection of PWM duty pulse polarity for each channel
- Period and duty cycle are double buffered. Change takes effect when the end of the effective period is reached (PWM counter reaches 0) or when the channel is disabled.
- Programmable center or left aligned outputs on individual channels
- Six 8-bit channel or three 16-bit channel PWM resolution
- Four clock sources (A, B, SA, and SB) provide for a wide range of frequencies.
- Programmable clock select logic
- Emergency shutdown

10.1.2 Modes of Operation

There is a software programmable option for low power consumption in wait mode that disables the input clock to the prescaler.

In freeze mode there is a software programmable option to disable the input clock to the prescaler. This is useful for emulation.
10.1.3 Block Diagram

Figure 10-1. PWM8B6CV1 Block Diagram

10.2 External Signal Description

The PWM8B6CV1 module has a total of six external pins.

10.2.1 PWM5 — Pulse Width Modulator Channel 5 Pin

This pin serves as waveform output of PWM channel 5 and as an input for the emergency shutdown feature.

10.2.2 PWM4 — Pulse Width Modulator Channel 4 Pin

This pin serves as waveform output of PWM channel 4.

10.2.3 PWM3 — Pulse Width Modulator Channel 3 Pin

This pin serves as waveform output of PWM channel 3.
10.2.4 **PWM2 — Pulse Width Modulator Channel 2 Pin**
This pin serves as waveform output of PWM channel 2.

10.2.5 **PWM1 — Pulse Width Modulator Channel 1 Pin**
This pin serves as waveform output of PWM channel 1.

10.2.6 **PWM0 — Pulse Width Modulator Channel 0 Pin**
This pin serves as waveform output of PWM channel 0.

10.3 **Memory Map and Register Definition**
This subsection describes in detail all the registers and register bits in the PWM8B6CV1 module.

The special-purpose registers and register bit functions that would not normally be made available to device end users, such as factory test control registers and reserved registers are clearly identified by means of shading the appropriate portions of address maps and register diagrams. Notes explaining the reasons for restricting access to the registers and functions are also explained in the individual register descriptions.

10.3.1 **Module Memory Map**
The following paragraphs describe the content of the registers in the PWM8B6CV1 module. The base address of the PWM8B6CV1 module is determined at the MCU level when the MCU is defined. The register decode map is fixed and begins at the first address of the module address offset. Table 10-1 shows the registers associated with the PWM and their relative offset from the base address. The register detail description follows the order in which they appear in the register map.

Reserved bits within a register will always read as 0 and the write will be unimplemented. Unimplemented functions are indicated by shading the bit. Table 10-1 shows the memory map for the PWM8B6CV1 module.

**NOTE**
Register address = base address + address offset, where the base address is defined at the MCU level and the address offset is defined at the module level.

Figure 10-2. PWM Register Summary (continued)
10.3.2.1 **PWM Enable Register (PWME)**

Each PWM channel has an enable bit (PWMEx) to start its waveform output. When any of the PWMEx bits are set (PWMEx = 1), the associated PWM output is enabled immediately. However, the actual PWM waveform is not available on the associated PWM output until its clock source begins its next cycle due to the synchronization of PWMEx and the clock source.

**NOTE**

The first PWM cycle after enabling the channel can be irregular.

An exception to this is when channels are concatenated. After concatenated mode is enabled (CONxx bits set in PWMCTL register), enabling/disabling the corresponding 16-bit PWM channel is controlled by the low-order PWMEx bit. In this case, the high-order bytes PWMEx bits have no effect and their corresponding PWM output lines are disabled.

While in run mode, if all six PWM channels are disabled (PWME5–PWME0 = 0), the prescaler counter shuts off for power savings.

![Figure 10-3. PWM Enable Register (PWME)](image)

Table 10-2. PWME Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 5 PWME5 | Pulse Width Channel 5 Enable  
0 Pulse width channel 5 is disabled.  
1 Pulse width channel 5 is enabled. The pulse modulated signal becomes available at PWM output bit 5 when its clock source begins its next cycle. |
| 4 PWME4 | Pulse Width Channel 4 Enable  
0 Pulse width channel 4 is disabled.  
1 Pulse width channel 4 is enabled. The pulse modulated signal becomes available at PWM output bit 4 when its clock source begins its next cycle. If CON45 = 1, then bit has no effect and PWM output line 4 is disabled. |
| 3 PWME3 | Pulse Width Channel 3 Enable  
0 Pulse width channel 3 is disabled.  
1 Pulse width channel 3 is enabled. The pulse modulated signal becomes available at PWM output bit 3 when its clock source begins its next cycle. |
| 2 PWME2 | Pulse Width Channel 2 Enable  
0 Pulse width channel 2 is disabled.  
1 Pulse width channel 2 is enabled. The pulse modulated signal becomes available at PWM output bit 2 when its clock source begins its next cycle. If CON23 = 1, then bit has no effect and PWM output line 2 is disabled. |
### PWM Polarity Register (PWMPOL)

The starting polarity of each PWM channel waveform is determined by the associated PPOLx bit in the PWMPOL register. If the polarity bit is 1, the PWM channel output is high at the beginning of the cycle and then goes low when the duty count is reached. Conversely, if the polarity bit is 0 the output starts low and then goes high when the duty count is reached.

#### Table 10-2. PWME Field Descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1 PWME1 | Pulse Width Channel 1 Enable  
0: Pulse width channel 1 is disabled.  
1: Pulse width channel 1 is enabled. The pulse modulated signal becomes available at PWM, output bit 1 when its clock source begins its next cycle. |
| 0 PWME0 | Pulse Width Channel 0 Enable  
0: Pulse width channel 0 is disabled.  
1: Pulse width channel 0 is enabled. The pulse modulated signal becomes available at PWM, output bit 0 when its clock source begins its next cycle. If CON01 = 1, then bit has no effect and PWM output line 0 is disabled. |

#### Table 10-3. PWMPOL Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>

</tr>
</thead>
</table>
| 5 PPOL5 | Pulse Width Channel 5 Polarity  
0: PWM channel 5 output is low at the beginning of the period, then goes high when the duty count is reached.  
1: PWM channel 5 output is high at the beginning of the period, then goes low when the duty count is reached. |
| 4 PPOL4 | Pulse Width Channel 4 Polarity  
0: PWM channel 4 output is low at the beginning of the period, then goes high when the duty count is reached.  
1: PWM channel 4 output is high at the beginning of the period, then goes low when the duty count is reached. |
### 10.3.2.3 PWM Clock Select Register (PWMCLK)

Each PWM channel has a choice of two clocks to use as the clock source for that channel as described below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PPOL3</td>
<td>Pulse Width Channel 3 Polarity</td>
</tr>
<tr>

</tr>
<tr>
<td>PPOL0</td>
<td>Pulse Width Channel 0 Polarity</td>
</tr>
<tr>
<td>0</td>
<td>PWM channel 0 output is low at the beginning of the period, then goes high when the duty count is reached.</td>
</tr>
<tr>
<td>1</td>
<td>PWM channel 0 output is high at the beginning of the period, then goes low when the duty count is reached.</td>
</tr>
</tbody>
</table>

**NOTE**

Register bits PCLK0 to PCLK5 can be written anytime. If a clock select is changed while a PWM signal is being generated, a truncated or stretched pulse can occur during the transition.
10.3.2.4 PWM Prescale Clock Select Register (PWMPRCLK)

This register selects the prescale clock source for clocks A and B independently.

![Figure 10-6. PWM Prescaler Clock Select Register (PWMPRCLK)](image)

Read: anytime  
Write: anytime

**NOTE**  
PCKB2–PCKB0 and PCKA2–PCKA0 register bits can be written anytime. If the clock prescale is changed while a PWM signal is being generated, a truncated or stretched pulse can occur during the transition.

---

Table 10-4. PWMCLK Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 5 PCLK5 | Pulse Width Channel 5 Clock Select  
0 Clock A is the clock source for PWM channel 5.

| 4 PCLK4 | Pulse Width Channel 4 Clock Select  
0 Clock A is the clock source for PWM channel 4.  
1 Clock SA is the clock source for PWM channel 4. |
| 3 PCLK3 | Pulse Width Channel 3 Clock Select  
0 Clock B is the clock source for PWM channel 3.  
1 Clock SB is the clock source for PWM channel 3. |
| 2 PCLK2 | Pulse Width Channel 2 Clock Select  
0 Clock B is the clock source for PWM channel 2.  
1 Clock SB is the clock source for PWM channel 2. |
| 1 PCLK1 | Pulse Width Channel 1 Clock Select  
0 Clock A is the clock source for PWM channel 1.  
1 Clock SA is the clock source for PWM channel 1. |
| 0 PCLK0 | Pulse Width Channel 0 Clock Select  
0 Clock A is the clock source for PWM channel 0.  
1 Clock SA is the clock source for PWM channel 0. |
10.3.2.5 PWM Center Align Enable Register (PWMC)

The PWMC register contains six control bits for the selection of center aligned outputs or left aligned outputs for each PWM channel. If the CAEx bit is set to a 1, the corresponding PWM output will be center aligned. If the CAEx bit is cleared, the corresponding PWM output will be left aligned. Reference Section 10.4.2.5, “Left Aligned Outputs,” and Section 10.4.2.6, “Center Aligned Outputs,” for a more detailed description of the PWM output modes.
NOTE

Write these bits only when the corresponding channel is disabled.

Table 10-8. PWMCAE Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 5 CAE5 | Center Aligned Output Mode on Channel 5  
0 Channel 5 operates in left aligned output mode.

| 4 CAE4 | Center Aligned Output Mode on Channel 4  
0 Channel 4 operates in left aligned output mode.  
1 Channel 4 operates in center aligned output mode. |
| 3 CAE3 | Center Aligned Output Mode on Channel 3  
0 Channel 3 operates in left aligned output mode.  
1 Channel 3 operates in center aligned output mode. |
| 2 CAE2 | Center Aligned Output Mode on Channel 2  
0 Channel 2 operates in left aligned output mode.  
1 Channel 2 operates in center aligned output mode. |
| 1 CAE1 | Center Aligned Output Mode on Channel 1  
0 Channel 1 operates in left aligned output mode.  
1 Channel 1 operates in center aligned output mode. |
| 0 CAE0 | Center Aligned Output Mode on Channel 0  
0 Channel 0 operates in left aligned output mode.  
1 Channel 0 operates in center aligned output mode. |

10.3.2.6 PWM Control Register (PWMCTL)

The PWMCTL register provides for various control of the PWM module.
There are three control bits for concatenation, each of which is used to concatenate a pair of PWM channels into one 16-bit channel. When channels 4 and 5 are concatenated, channel 4 registers become the high-order bytes of the double-byte channel. When channels 2 and 3 are concatenated, channel 2 registers become the high-order bytes of the double-byte channel. When channels 0 and 1 are concatenated, channel 0 registers become the high-order bytes of the double-byte channel.

Reference Section 10.4.2.7, “PWM 16-Bit Functions,” for a more detailed description of the concatenation PWM function.

**NOTE**

Change these bits only when both corresponding channels are disabled.
### 10.3.2.7 Reserved Register (PWMTST)

This register is reserved for factory testing of the PWM module and is not available in normal modes.

```

<td>2 PFRZ</td>
<td>PWM Counters Stop in Freeze Mode</td>
</tr>
</tbody>
</table>
- 0: Allow PWM to continue while in freeze mode.
- 1: Disable PWM input clock to the prescaler whenever the part is in freeze mode. This is useful for emulation.

#### 10.3.2.7.1 Reserved Register (PWMTST)

This register is reserved for factory testing of the PWM module and is not available in normal modes.

```
<table>
<thead>
<tr>
<th>R</th>
<th>W</th>
<th>Reset</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0 0 0 0 0 0</td>
</tr>
</tbody>
</table>
```

![Figure 10-9. Reserved Register (PWMTST)](image-url)
Read: always read 0x0000 in normal modes
Write: unimplemented in normal modes

NOTE
Writing to this register when in special modes can alter the PWM functionality.

10.3.2.8 Reserved Register (PWMPRSC)
This register is reserved for factory testing of the PWM module and is not available in normal modes.

![Reserved Register (PWMPRSC)](figure)

Read: always read 0x0000 in normal modes
Write: unimplemented in normal modes

NOTE
Writing to this register when in special modes can alter the PWM functionality.

10.3.2.9 PWM Scale A Register (PWMSCLA)
PWMSCLA is the programmable scale value used in scaling clock A to generate clock SA. Clock SA is generated by taking clock A, dividing it by the value in the PWMSCLA register and dividing that by two.

\[
\text{Clock SA} = \frac{\text{Clock A}}{2 \times \text{PWMSCLA}}
\]

NOTE
When PWMSCLA = 0x0000, PWMSCLA value is considered a full scale value of 256. Clock A is thus divided by 512.

Any value written to this register will cause the scale counter to load the new scale value (PWMSCLA).
Read: anytime
Write: anytime (causes the scale counter to load the PWMSCLA value)

10.3.2.10 PWM Scale B Register (PWMSCLB)

PWMSCLB is the programmable scale value used in scaling clock B to generate clock SB. Clock SB is generated by taking clock B, dividing it by the value in the PWMSCLB register and dividing that by two.

\[
\text{Clock SB} = \frac{\text{Clock B}}{2 \times \text{PWMSCLB}}
\]

**NOTE**

When PWMSCLB = 0x0000, PWMSCLB value is considered a full scale value of 256. Clock B is thus divided by 512.

Any value written to this register will cause the scale counter to load the new scale value (PWMSCLB).

[Figure 10-12. PWM Scale B Register (PWMSCLB)]

Read: anytime
Write: anytime (causes the scale counter to load the PWMSCLB value).

10.3.2.11 Reserved Registers (PWMSCNTx)

The registers PWMSCNTA and PWMSCNTB are reserved for factory testing of the PWM module and are not available in normal modes.

[Figure 10-13. Reserved Register (PWMSCNTA)]
10.3.2.12 PWM Channel Counter Registers (PWMCNTx)

Each channel has a dedicated 8-bit up/down counter which runs at the rate of the selected clock source. The counter can be read at any time without affecting the count or the operation of the PWM channel. In left aligned output mode, the counter counts from 0 to the value in the period register – 1. In center aligned output mode, the counter counts from 0 up to the value in the period register and then back down to 0.

Any value written to the counter causes the counter to reset to 0x0000, the counter direction to be set to up, the immediate load of both duty and period registers with values from the buffers, and the output to change according to the polarity bit. The counter is also cleared at the end of the effective period (see Section 10.4.2.5, “Left Aligned Outputs,” and Section 10.4.2.6, “Center Aligned Outputs,” for more details). When the channel is disabled (PWMEx = 0), the PWMCNTx register does not count. When a channel becomes enabled (PWMEx = 1), the associated PWM counter starts at the count in the PWMCNTx register. For more detailed information on the operation of the counters, reference Section 10.4.2.4, “PWM Timer Counters.”

In concatenated mode, writes to the 16-bit counter by using a 16-bit access or writes to either the low- or high-order byte of the counter will reset the 16-bit counter. Reads of the 16-bit counter must be made by 16-bit access to maintain data coherency.

NOTE

Writing to the counter while the channel is enabled can cause an irregular PWM cycle to occur.

**Figure 10-19. PWM Channel Counter Registers (PWMCNT4)**
10.3.2.13 PWM Channel Period Registers (PWMPERx)

There is a dedicated period register for each channel. The value in this register determines the period of the associated PWM channel.

The period registers for each channel are double buffered so that if they change while the channel is enabled, the change will NOT take effect until one of the following occurs:

- The effective period ends
- The counter is written (counter resets to 0x0000)
- The channel is disabled

In this way, the output of the PWM will always be either the old waveform or the new waveform, not some variation in between. If the channel is not enabled, then writes to the period register will go directly to the latches as well as the buffer.

**NOTE**

Reads of this register return the most recent value written. Reads do not necessarily return the value of the currently active period due to the double buffering scheme.

Reference Section 10.4.2.3, “PWM Period and Duty,” for more information.

To calculate the output period, take the selected clock source period for the channel of interest (A, B, SA, or SB) and multiply it by the value in the period register for that channel:

- Left aligned output (CAEx = 0)
- PWMx period = channel clock period * PWMPERx
- Center aligned output (CAEx = 1)
- PWMx period = channel clock period * (2 * PWMPERx)

For boundary case programming values, please refer to Section 10.4.2.8, “PWM Boundary Cases.”

---

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor
10.3.2.14 PWM Channel Duty Registers (PWMDTYx)

There is a dedicated duty register for each channel. The value in this register determines the duty of the associated PWM channel. The duty value is compared to the counter and if it is equal to the counter value a match occurs and the output changes state.

The duty registers for each channel are double buffered so that if they change while the channel is enabled, the change will NOT take effect until one of the following occurs:

- The effective period ends
- The counter is written (counter resets to 0x0000)
- The channel is disabled

In this way, the output of the PWM will always be either the old duty waveform or the new duty waveform, not some variation in between. If the channel is not enabled, then writes to the duty register will go directly to the latches as well as the buffer.

NOTE
Reads of this register return the most recent value written. Reads do not necessarily return the value of the currently active duty due to the double buffering scheme.

Reference Section 10.4.2.3, “PWM Period and Duty,” for more information.

NOTE
Depending on the polarity bit, the duty registers will contain the count of either the high time or the low time. If the polarity bit is 1, the output starts high and then goes low when the duty count is reached, so the duty registers contain a count of the high time. If the polarity bit is 0, the output starts low and then goes high when the duty count is reached, so the duty registers contain a count of the low time.

To calculate the output duty cycle (high time as a % of period) for a particular channel:

- Polarity = 0 (PPOLx = 0)
  Duty cycle = [(PWMPERx PWMDTYx)/PWMPERx] * 100%
- Polarity = 1 (PPOLx = 1)
  Duty cycle = [PWMDTYx / PWMPERx] * 100%
For boundary case programming values, please refer to Section 10.4.2.8, “PWM Boundary Cases.”

<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 PWMIF | **PWM Interrupt Flag** — Any change from passive to asserted (active) state or from active to passive state will be flagged by setting the PWMIF flag = 1. The flag is cleared by writing a logic 1 to it. Writing a 0 has no effect.  
   0 No change on PWM5IN input.  
   1 Change on PWM5IN input |
| 6 PWMIE | **PWM Interrupt Enable** — If interrupt is enabled an interrupt to the CPU is asserted.  
   0 PWM interrupt is disabled.  
   1 PWM interrupt is enabled. |
| 5 PWMRSTRT | **PWM Restart** — The PWM can only be restarted if the PWM channel input 5 is deasserted. After writing a logic 1 to the PWMRSTRT bit (trigger event) the PWM channels start running after the corresponding counter passes next “counter = 0” phase.  
   Also, if the PWMSENA bit is reset to 0, the PWM do not start before the counter passes 0x0000.  
   The bit is always read as 0. |
| 4 PWMLVL | **PWM Shutdown Output Level** — If active level as defined by the PWM5IN input, gets asserted all enabled PWM channels are immediately driven to the level defined by PWMLVL.  
   0 PWM outputs are forced to 0  
   1 PWM outputs are forced to 1. |
10.4 Functional Description

10.4.1 PWM Clock Select

There are four available clocks called clock A, clock B, clock SA (scaled A), and clock SB (scaled B). These four clocks are based on the bus clock.

Clock A and B can be software selected to be 1, 1/2, 1/4, 1/8, ..., 1/64, 1/128 times the bus clock. Clock SA uses clock A as an input and divides it further with a reloadable counter. Similarly, clock SB uses clock B as an input and divides it further with a reloadable counter. The rates available for clock SA are software selectable to be clock A divided by 2, 4, 6, 8, ..., or 512 in increments of divide by 2. Similar rates are available for clock SB. Each PWM channel has the capability of selecting one of two clocks, either the pre-scaled clock (clock A or B) or the scaled clock (clock SA or SB).

The block diagram in Figure 10-34 shows the four different clocks and how the scaled clocks are created.

10.4.1.1 Prescale

The input clock to the PWM prescaler is the bus clock. It can be disabled whenever the part is in freeze mode by setting the PFRZ bit in the PWMCTL register. If this bit is set, whenever the MCU is in freeze mode the input clock to the prescaler is disabled. This is useful for emulation in order to freeze the PWM. The input clock can also be disabled when all six PWM channels are disabled (PWME5–PWME0 = 0). This is useful for reducing power by disabling the prescale counter.

Clock A and clock B are scaled values of the input clock. The value is software selectable for both clock A and clock B and has options of 1, 1/2, 1/4, 1/8, 1/16, 1/32, 1/64, or 1/128 times the bus clock. The value selected for clock A is determined by the PCKA2, PCKA1, and PCKA0 bits in the PWMPRCLK register. The value selected for clock B is determined by the PCKB2, PCKB1, and PCKB0 bits also in the PWMPRCLK register.

</tbody>
</table>
Figure 10-34. PWM Clock Select Block Diagram
10.4.1.2 Clock Scale

The scaled A clock uses clock A as an input and divides it further with a user programmable value and then divides this by 2. The scaled B clock uses clock B as an input and divides it further with a user programmable value and then divides this by 2. The rates available for clock SA are software selectable to be clock A divided by 2, 4, 6, 8, ..., or 512 in increments of divide by 2. Similar rates are available for clock SB.

Clock A is used as an input to an 8-bit down counter. This down counter loads a user programmable scale value from the scale register (PWMSCLA). When the down counter reaches 1, two things happen; a pulse is output and the 8-bit counter is re-loaded. The output signal from this circuit is further divided by two. This gives a greater range with only a slight reduction in granularity. Clock SA equals clock A divided by two times the value in the PWMSCLA register.

NOTE

Clock SA = Clock A / (2 * PWMSCLA)

When PWMSCLA = 0x0000, PWMSCLA value is considered a full scale value of 256. Clock A is thus divided by 512.

Similarly, clock B is used as an input to an 8-bit down counter followed by a divide by two producing clock SB. Thus, clock SB equals clock B divided by two times the value in the PWMSCLB register.

NOTE

Clock SB = Clock B / (2 * PWMSCLB)

When PWMSCLB = 0x0000, PWMSCLB value is considered a full scale value of 256. Clock B is thus divided by 512.

As an example, consider the case in which the user writes 0x00FF into the PWMSCLA register. Clock A for this case will be bus clock divided by 4. A pulse will occur at a rate of once every 255 x 4 bus cycles. Passing this through the divide by two circuit produces a clock signal at a bus clock divided by 2040 rate. Similarly, a value of 0x0001 in the PWMSCLA register when clock A is bus clock divided by 4 will produce a bus clock divided by 8 rate.

Writing to PWMSCLA or PWMSCLB causes the associated 8-bit down counter to be re-loaded. Otherwise, when changing rates the counter would have to count down to 0x0001 before counting at the proper rate. Forcing the associated counter to re-load the scale register value every time PWMSCLA or PWMSCLB is written prevents this.

NOTE

Writing to the scale registers while channels are operating can cause irregularities in the PWM outputs.

10.4.1.3 Clock Select

Each PWM channel has the capability of selecting one of two clocks. For channels 0, 1, 4, and 5 the clock choices are clock A or clock SA. For channels 2 and 3 the choices are clock B or clock SB. The clock selection is done with the PCLKx control bits in the PWMCLK register.
NOTE
Changing clock control bits while channels are operating can cause irregularities in the PWM outputs.

10.4.2 PWM Channel Timers

The main part of the PWM module are the actual timers. Each of the timer channels has a counter, a period register and a duty register (each are 8 bit). The waveform output period is controlled by a match between the period register and the value in the counter. The duty is controlled by a match between the duty register and the counter value and causes the state of the output to change during the period. The starting polarity of the output is also selectable on a per channel basis. Figure 10-35 shows a block diagram for PWM timer.

![Figure 10-35. PWM Timer Channel Block Diagram](image-url)

10.4.2.1 PWM Enable

Each PWM channel has an enable bit (PWMEx) to start its waveform output. When any of the PWMEx bits are set (PWMEx = 1), the associated PWM output signal is enabled immediately. However, the actual PWM waveform is not available on the associated PWM output until its clock source begins its next cycle.

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor 355
due to the synchronization of PWMEx and the clock source. An exception to this is when channels are concatenated. Refer to Section 10.4.2.7, “PWM 16-Bit Functions,” for more detail.

**NOTE**

The first PWM cycle after enabling the channel can be irregular.

On the front end of the PWM timer, the clock is enabled to the PWM circuit by the PWMEx bit being high. There is an edge-synchronizing circuit to guarantee that the clock will only be enabled or disabled at an edge. When the channel is disabled (PWMEx = 0), the counter for the channel does not count.

### 10.4.2.2 PWM Polarity

Each channel has a polarity bit to allow starting a waveform cycle with a high or low signal. This is shown on the block diagram as a mux select of either the Q output or the Q̅ output of the PWM output flip-flop. When one of the bits in the PWMPOL register is set, the associated PWM channel output is high at the beginning of the waveform, then goes low when the duty count is reached. Conversely, if the polarity bit is 0, the output starts low and then goes high when the duty count is reached.

### 10.4.2.3 PWM Period and Duty

Dedicated period and duty registers exist for each channel and are double buffered so that if they change while the channel is enabled, the change will NOT take effect until one of the following occurs:

- The effective period ends
- The counter is written (counter resets to 0x0000)
- The channel is disabled

In this way, the output of the PWM will always be either the old waveform or the new waveform, not some variation in between. If the channel is not enabled, then writes to the period and duty registers will go directly to the latches as well as the buffer.

A change in duty or period can be forced into effect “immediately” by writing the new value to the duty and/or period registers and then writing to the counter. This forces the counter to reset and the new duty and/or period values to be latched. In addition, because the counter is readable it is possible to know where the count is with respect to the duty value and software can be used to make adjustments.

**NOTE**

When forcing a new period or duty into effect immediately, an irregular PWM cycle can occur.

Depending on the polarity bit, the duty registers will contain the count of either the high time or the low time.

### 10.4.2.4 PWM Timer Counters

Each channel has a dedicated 8-bit up/down counter which runs at the rate of the selected clock source (reference Figure 10-34 for the available clock sources and rates). The counter compares to two registers, a duty register and a period register as shown in Figure 10-35. When the PWM counter matches the duty register the output flip-flop changes state causing the PWM waveform to also change state. A match
between the PWM counter and the period register behaves differently depending on what output mode is selected as shown in Figure 10-35 and described in Section 10.4.2.5, “Left Aligned Outputs,” and Section 10.4.2.6, “Center Aligned Outputs.”

Each channel counter can be read at anytime without affecting the count or the operation of the PWM channel.

Any value written to the counter causes the counter to reset to 0x0000, the counter direction to be set to up, the immediate load of both duty and period registers with values from the buffers, and the output to change according to the polarity bit. When the channel is disabled (PWMEx = 0), the counter stops. When a channel becomes enabled (PWMEx = 1), the associated PWM counter continues from the count in the PWMCNTx register. This allows the waveform to resume when the channel is re-enabled. When the channel is disabled, writing 0 to the period register will cause the counter to reset on the next selected clock.

**NOTE**

If the user wants to start a new “clean” PWM waveform without any “history” from the old waveform, the user must write to channel counter (PWMCNTx) prior to enabling the PWM channel (PWMEx = 1).

Generally, writes to the counter are done prior to enabling a channel to start from a known state. However, writing a counter can also be done while the PWM channel is enabled (counting). The effect is similar to writing the counter when the channel is disabled except that the new period is started immediately with the output set according to the polarity bit.

**NOTE**

Writing to the counter while the channel is enabled can cause an irregular PWM cycle to occur.

The counter is cleared at the end of the effective period (see Section 10.4.2.5, “Left Aligned Outputs,” and Section 10.4.2.6, “Center Aligned Outputs,” for more details).

**10.4.2.5 Left Aligned Outputs**

The PWM timer provides the choice of two types of outputs, left aligned or center aligned outputs. They are selected with the CAEx bits in the PWMCAE register. If the CAEx bit is cleared (CAEx = 0), the corresponding PWM output will be left aligned.

In left aligned output mode, the 8-bit counter is configured as an up counter only. It compares to two registers, a duty register and a period register as shown in the block diagram in Figure 10-35. When the...
Pulse-Width Modulator (PWM8B6CV1) Block Description

PWM counter matches the duty register the output flip-flop changes state causing the PWM waveform to also change state. A match between the PWM counter and the period register resets the counter and the output flip-flop as shown in Figure 10-35 as well as performing a load from the double buffer period and duty register to the associated registers as described in Section 10.4.2.3, “PWM Period and Duty.” The counter counts from 0 to the value in the period register – 1.

NOTE
Changing the PWM output mode from left aligned output to center aligned output (or vice versa) while channels are operating can cause irregularities in the PWM output. It is recommended to program the output mode before enabling the PWM channel.

To calculate the output frequency in left aligned output mode for a particular channel, take the selected clock source frequency for the channel (A, B, SA, or SB) and divide it by the value in the period register for that channel.

- PWMx frequency = clock (A, B, SA, or SB) / PWMPERx
- PWMx duty cycle (high time as a% of period):
  - Polarity = 0 (PPOLx = 0)
    Duty cycle = [(PWMPERx-PWMDTYx)/PWMPERx] * 100%
  - Polarity = 1 (PPOLx = 1)
    Duty cycle = [PWMDTYx / PWMPERx] * 100%

As an example of a left aligned output, consider the following case:
Clock source = bus clock, where bus clock = 10 MHz (100 ns period)
PPOLx = 0
PWMPERx = 4
PWMDTYx = 1
PWMx frequency = 10 MHz/4 = 2.5 MHz
PWMx period = 400 ns
PWMx duty cycle = 3/4 *100% = 75%

Shown below is the output waveform generated.
10.4.2.6 Center Aligned Outputs

For center aligned output mode selection, set the CAEx bit (CAEx = 1) in the PWMCAE register and the corresponding PWM output will be center aligned.

The 8-bit counter operates as an up/down counter in this mode and is set to up whenever the counter is equal to 0x0000. The counter compares to two registers, a duty register and a period register as shown in the block diagram in Figure 10-35. When the PWM counter matches the duty register the output flip-flop changes state causing the PWM waveform to also change state. A match between the PWM counter and the period register changes the counter direction from an up-count to a down-count. When the PWM counter decrements and matches the duty register again, the output flip-flop changes state causing the PWM output to also change state. When the PWM counter decrements and reaches 0, the counter direction changes from a down-count back to an up-count and a load from the double buffer period and duty registers to the associated registers is performed as described in Section 10.4.2.3, “PWM Period and Duty.” The counter counts from 0 up to the value in the period register and then back down to 0. Thus the effective period is PWMPERx*2.

**NOTE**
Changing the PWM output mode from left aligned output to center aligned output (or vice versa) while channels are operating can cause irregularities in the PWM output. It is recommended to program the output mode before enabling the PWM channel.

To calculate the output frequency in center aligned output mode for a particular channel, take the selected clock source frequency for the channel (A, B, SA, or SB) and divide it by twice the value in the period register for that channel.

- \[ \text{PWMx frequency} = \frac{\text{clock (A, B, SA, or SB)}}{2 \times \text{PWMPERx}} \]
• PWMx duty cycle (high time as a% of period):
  — Polarity = 0 (PPOLx = 0)
    Duty cycle = [(PWMPERx-PWMDTYx)/PWMPERx] * 100%
  — Polarity = 1 (PPOLx = 1)
    Duty cycle = [PWMDTYx / PWMPERx] * 100%

As an example of a center aligned output, consider the following case:
Clock source = bus clock, where bus clock = 10 MHz (100 ns period)
PPOLx = 0
PWMPERx = 4
PWMDTYx = 1
PWMx frequency = 10 MHz/8 = 1.25 MHz
PWMx period = 800 ns
PWMx duty cycle = 3/4 *100% = 75%

Shown below is the output waveform generated.

![Figure 10-39. PWM Center Aligned Output Example Waveform](image)

10.4.2.7 PWM 16-Bit Functions

The PWM timer also has the option of generating 6-channels of 8-bits or 3-channels of 16-bits for greater PWM resolution}. This 16-bit channel option is achieved through the concatenation of two 8-bit channels.

The PWMCTL register contains three control bits, each of which is used to concatenate a pair of PWM channels into one 16-bit channel. Channels 4 and 5 are concatenated with the CON45 bit, channels 2 and 3 are concatenated with the CON23 bit, and channels 0 and 1 are concatenated with the CON01 bit.

NOTE

Change these bits only when both corresponding channels are disabled.

When channels 4 and 5 are concatenated, channel 4 registers become the high-order bytes of the double byte channel as shown in Figure 10-40. Similarly, when channels 2 and 3 are concatenated, channel 2 registers become the high-order bytes of the double byte channel. When channels 0 and 1 are concatenated, channel 0 registers become the high-order bytes of the double byte channel.
When using the 16-bit concatenated mode, the clock source is determined by the low-order 8-bit channel clock select control bits. That is channel 5 when channels 4 and 5 are concatenated, channel 3 when channels 2 and 3 are concatenated, and channel 1 when channels 0 and 1 are concatenated. The resulting PWM is output to the pins of the corresponding low-order 8-bit channel as also shown in Figure 10-40. The polarity of the resulting PWM output is controlled by the PPOLx bit of the corresponding low-order 8-bit channel as well.

After concatenated mode is enabled (CONxx bits set in PWMCTL register), enabling/disabling the corresponding 16-bit PWM channel is controlled by the low-order PWMEx bit. In this case, the high-order bytes PWMEx bits have no effect and their corresponding PWM output is disabled.

In concatenated mode, writes to the 16-bit counter by using a 16-bit access or writes to either the low or high-order byte of the counter will reset the 16-bit counter. Reads of the 16-bit counter must be made by 16-bit access to maintain data coherency.

Either left aligned or center aligned output mode can be used in concatenated mode and is controlled by the low-order CAEx bit. The high-order CAEx bit has no effect.
Table 10-12 is used to summarize which channels are used to set the various control bits when in 16-bit mode.

1. Counter = 0x0000 and does not count.

### 10.5 Resets

The reset state of each individual bit is listed within the register description section (see Section 10.3, “Memory Map and Register Definition,” which details the registers and their bit-fields. All special functions or modes which are initialized during or just following reset are described within this section.

- The 8-bit up/down counter is configured as an up counter out of reset.
- All the channels are disabled and all the counters don’t count.

### 10.6 Interrupts

The PWM8B6CV1 module has only one interrupt which is generated at the time of emergency shutdown, if the corresponding enable bit (PWMIE) is set. This bit is the enable for the interrupt. The interrupt flag PWMIF is set whenever the input level of the PWM5 channel changes while PWM5ENA=1 or when PWMENA is being asserted while the level at PWM5 is active.

A description of the registers involved and affected due to this interrupt is explained in Section 10.3.2.15, “PWM Shutdown Register (PWMSDN).”
Chapter 11
Serial Communication Interface (S12SCIV5)

11.1 Introduction

This block guide provides an overview of the serial communication interface (SCI) module. The SCI allows asynchronous serial communications with peripheral devices and other CPUs.

11.1.1 Glossary

IR: InfraRed
IrDA: Infrared Design Associate
IRQ: Interrupt Request
LIN: Local Interconnect Network
LSB: Least Significant Bit
MSB: Most Significant Bit
NRZ: Non-Return-to-Zero
RZI: Return-to-Zero-Inverted
RXD: Receive Pin
SCI: Serial Communication Interface
TXD: Transmit Pin

11.1.2 Features

The SCI includes these distinctive features:

- Full-duplex or single-wire operation
- Standard mark/space non-return-to-zero (NRZ) format
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse widths
- 13-bit baud rate selection
- Programmable 8-bit or 9-bit data format
- Separately enabled transmitter and receiver
- Programmable polarity for transmitter and receiver
- Programmable transmitter output parity
- Two receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
- Interrupt-driven operation with eight flags:
  - Transmitter empty
  - Transmission complete
  - Receiver full
  - Idle receiver input
  - Receiver overrun
  - Noise error
  - Framing error
  - Parity error
  - Receive wakeup on active edge
  - Transmit collision detect supporting LIN
  - Break Detect supporting LIN
- Receiver framing error detection
- Hardware parity checking
- 1/16 bit-time noise detection

11.1.3 Modes of Operation

The SCI functions the same in normal, special, and emulation modes. It has two low power modes, wait and stop modes.

- Run mode
- Wait mode
- Stop mode
11.1.4 Block Diagram

Figure 11-1 is a high level block diagram of the SCI module, showing the interaction of various function blocks.

![Figure 11-1. SCI Block Diagram](image)

11.2 External Signal Description

The SCI module has a total of two external pins.

11.2.1 TXD — Transmit Pin

The TXD pin transmits SCI (standard or infrared) data. It will idle high in either mode and is high impedance anytime the transmitter is disabled.

11.2.2 RXD — Receive Pin

The RXD pin receives SCI (standard or infrared) data. An idle line is detected as a line high. This input is ignored when the receiver is disabled and should be terminated to a known voltage.

11.3 Memory Map and Register Definition

This section provides a detailed description of all the SCI registers.
11.3.1 Module Memory Map and Register Definition

The memory map for the SCI module is given below in Figure 11-2. The address listed for each register is the address offset. The total address for each register is the sum of the base address for the SCI module and the address offset for each register.

11.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Writes to a reserved register locations do not have any effect and reads of these locations return a zero. Details of register bit and field function follow the register diagrams, in bit order.

= Unimplemented or Reserved

Figure 11-2. SCI Register Summary (Sheet 1 of 2)
1. These registers are accessible if the AMAP bit in the SCISR2 register is set to zero.
2. These registers are accessible if the AMAP bit in the SCISR2 register is set to one.

= Unimplemented or Reserved

11.3.2.1 SCI Baud Rate Registers (SCIBDH, SCIBDL)

Read: Anytime, if AMAP = 0. If only SCIBDH is written to, a read will not return the correct data until SCIBDL is written to as well, following a write to SCIBDH.

Write: Anytime, if AMAP = 0.

NOTE

Those two registers are only visible in the memory map if AMAP = 0 (reset condition).

The SCI baud rate register is used to determine the baud rate of the SCI, and to control the infrared modulation/demodulation submodule.

### 11.3.2.2 SCI Control Register 1 (SCICR1)

#### Figure 11-5. SCI Control Register 1 (SCICR1)

Read: Anytime, if AMAP = 0.

Write: Anytime, if AMAP = 0.

**NOTE**

This register is only visible in the memory map if AMAP = 0 (reset condition).
Table 11-4. SCICR1 Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 LOOPS | Loop Select Bit — LOOPS enables loop operation. In loop operation, the RXD pin is disconnected from the SCI and the transmitter output is internally connected to the receiver input. Both the transmitter and the receiver must be enabled to use the loop function.  
0 Normal operation enabled  
1 Loop operation enabled  
The receiver input is determined by the RSRC bit. |
| 6 SCISWAI | SCI Stop in Wait Mode Bit — SCISWAI disables the SCI in wait mode.  
0 SCI enabled in wait mode  
1 SCI disabled in wait mode |
| 5 RSRC | Receiver Source Bit — When LOOPS = 1, the RSRC bit determines the source for the receiver shift register input. See Table 11-5.  
0 Receiver input internally connected to transmitter output  
1 Receiver input connected externally to transmitter |
| 4 M | Data Format Mode Bit — MODE determines whether data characters are eight or nine bits long.  
0 One start bit, eight data bits, one stop bit  
1 One start bit, nine data bits, one stop bit |
| 3 WAKE | Wakeup Condition Bit — WAKE determines which condition wakes up the SCI: a logic 1 (address mark) in the most significant bit position of a received data character or an idle condition on the RXD pin.  
0 Idle line wakeup  
1 Address mark wakeup |
| 2 ILT | Idle Line Type Bit — ILT determines when the receiver starts counting logic 1s as idle character bits. The counting begins either after the start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit may cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.  
0 Idle character bit count begins after start bit  
1 Idle character bit count begins after stop bit |
| 1 PE | Parity Enable Bit — PE enables the parity function. When enabled, the parity function inserts a parity bit in the most significant bit position.  
0 Parity function disabled  
1 Parity function enabled |
| 0 PT | Parity Type Bit — PT determines whether the SCI generates and checks for even parity or odd parity. With even parity, an even number of 1s clears the parity bit and an odd number of 1s sets the parity bit. With odd parity, an odd number of 1s clears the parity bit and an even number of 1s sets the parity bit.  
0 Even parity  
1 Odd parity |

#### Table 11-10. SCICR2 Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 TIE | Transmitter Interrupt Enable Bit — TIE enables the transmit data register empty flag, TDRE, to generate interrupt requests.  
0 TDRE interrupt requests disabled  
1 TDRE interrupt requests enabled |
| 6 TCIE | Transmission Complete Interrupt Enable Bit — TCIE enables the transmission complete flag, TC, to generate interrupt requests.  
0 TC interrupt requests disabled  
1 TC interrupt requests enabled |
| 5 RIE | Receiver Full Interrupt Enable Bit — RIE enables the receive data register full flag, RDRF, or the overrun flag, OR, to generate interrupt requests.  
0 RDRF and OR interrupt requests disabled  
1 RDRF and OR interrupt requests enabled |
| 4 ILIE | Idle Line Interrupt Enable Bit — ILIE enables the idle line flag, IDLE, to generate interrupt requests.  
0 IDLE interrupt requests disabled  
1 IDLE interrupt requests enabled |
| 3 TE | Transmitter Enable Bit — TE enables the SCI transmitter and configures the TXD pin as being controlled by the SCI. The TE bit can be used to queue an idle preamble.  
0 Transmitter disabled  
1 Transmitter enabled |
| 2 RE | Receiver Enable Bit — RE enables the SCI receiver.  
0 Receiver disabled  
1 Receiver enabled |
| 1 RWU | Receiver Wakeup Bit — Standby state  
0 Normal operation.  
1 RWU enables the wakeup function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU. |
| 0 SBK | Send Break Bit — Toggling SBK sends one break character (10 or 11 logic 0s, respectively 13 or 14 logics 0s if BRK13 is set). Toggling implies clearing the SBK bit before the break character has finished transmitting. As long as SBK is set, the transmitter continues to send complete break characters (10 or 11 bits, respectively 13 or 14 bits).  
0 No break characters  
1 Transmit break characters |
11.3.2.7 SCI Status Register 1 (SCISR1)

The SCISR1 and SCISR2 registers provides inputs to the MCU for generation of SCI interrupts. Also, these registers can be polled by the MCU to check the status of these bits. The flag-clearing procedures require that the status register be read followed by a read or write to the SCI data register. It is permissible to execute other instructions between the two steps as long as it does not compromise the handling of I/O, but the order of operations is important for flag clearing.

Read: Anytime
Write: Has no meaning or effect

![Figure 11-10. SCI Status Register 1 (SCISR1)](image)

**Table 11-11. SCISR1 Field Descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>

<tr>
<td>7 TDRE</td>
<td><strong>Transmit Data Register Empty Flag</strong> — TDRE is set when the transmit shift register receives a byte from the SCI data register. When TDRE is 1, the transmit data register (SCIDRH/L) is empty and can receive a new value to transmit. Clear TDRE by reading SCI status register 1 (SCISR1), with TDRE set and then writing to SCI data register low (SCIDRL).&lt;br&gt;0: No byte transferred to transmit shift register&lt;br&gt;1: Byte transferred to transmit shift register; transmit data register empty</td>
</tr>
<tr>
<td>6 TC</td>
<td><strong>Transmit Complete Flag</strong> — TC is set low when there is a transmission in progress or when a preamble or break character is loaded. TC is set high when the TDRE flag is set and no data, preamble, or break character is being transmitted. When TC is set, the TXD pin becomes idle (logic 1). Clear TC by reading SCI status register 1 (SCISR1) with TC set and then writing to SCI data register low (SCIDRL). TC is cleared automatically when data, preamble, or break is queued and ready to be sent. TC is cleared in the event of a simultaneous set and clear of the TC flag (transmission not complete).&lt;br&gt;0: Transmission in progress&lt;br&gt;1: No transmission in progress</td>
</tr>
<tr>
<td>5 RDRF</td>
<td><strong>Receive Data Register Full Flag</strong> — RDRF is set when the data in the receive shift register transfers to the SCI data register. Clear RDRF by reading SCI status register 1 (SCISR1) with RDRF set and then reading SCI data register low (SCIDRL).&lt;br&gt;0: Data not available in SCI data register&lt;br&gt;1: Received data available in SCI data register</td>
</tr>
<tr>
<td>4 IDLE</td>
<td><strong>Idle Line Flag</strong> — IDLE is set when 10 consecutive logic 1s (if M = 0) or 11 consecutive logic 1s (if M = 1) appear on the receiver input. Once the IDLE flag is cleared, a valid frame must again set the RDRF flag before an idle condition can set the IDLE flag. Clear IDLE by reading SCI status register 1 (SCISR1) with IDLE set and then reading SCI data register low (SCIDRL).&lt;br&gt;0: Receiver input is either active now or has never become active since the IDLE flag was last cleared&lt;br&gt;1: Receiver input has become idle&lt;br&gt;Note: When the receiver wakeup bit (RWU) is set, an idle line condition does not set the IDLE flag.</td>
</tr>
</tbody>
</table>
### 11.3.2.8 SCI Status Register 2 (SCISR2)

<td>T7:T0 — Transmit bits seven through zero for 9-bit or 8-bit formats</td>
</tr>
</tbody>
</table>

**NOTE**

If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten. The same value is transmitted until T8 is rewritten.

In 8-bit data format, only SCI data register low (SCIDRL) needs to be accessed.

When transmitting in 9-bit data format and using 8-bit write instructions, write first to SCI data register high (SCIDRH), then SCIDRL.

### 11.4 Functional Description

This section provides a complete functional description of the SCI block, detailing the operation of the design from the end user perspective in a number of subsections.

Figure 11-14 shows the structure of the SCI module. The SCI allows full duplex, asynchronous, serial communication between the CPU and remote devices, including other CPUs. The SCI transmitter and receiver operate independently, although they use the same baud rate generator. The CPU monitors the status of the SCI, writes the data to be transmitted, and processes received data.
11.4.1 Infrared Interface Submodule

This module provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the SCI. The IrDA physical layer specification defines a half-duplex infrared communication link for exchange data. The full standard includes data rates up to 16 Mbits/s. This design covers only data rates between 2.4 Kbits/s and 115.2 Kbits/s.

The infrared submodule consists of two major blocks: the transmit encoder and the receive decoder. The SCI transmits serial bits of data which are encoded by the infrared submodule to transmit a narrow pulse.

---

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor

377
for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses should be
detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder (external
from the MCU). The narrow pulses are then stretched by the infrared submodule to get back to a serial bit
stream to be received by the SCI. The polarity of transmitted pulses and expected receive pulses can be
inverted so that a direct connection can be made to external IrDA transceiver modules that uses active low
pulses.

The infrared submodule receives its clock sources from the SCI. One of these two clocks are selected in
the infrared submodule in order to generate either 3/16, 1/16, 1/32 or 1/4 narrow pulses during
transmission. The infrared block receives two clock sources from the SCI, R16XCLK and R32XCLK,
which are configured to generate the narrow pulse width during transmission. The R16XCLK and
R32XCLK are internal clocks with frequencies 16 and 32 times the baud rate respectively. Both
R16XCLK and R32XCLK clocks are used for transmitting data. The receive decoder uses only the
R16XCLK clock.

11.4.1.1 Infrared Transmit Encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD pin. A
narrow pulse is transmitted for a zero bit and no pulse for a one bit. The narrow pulse is sent in the middle
of the bit with a duration of 1/32, 1/16, 3/16 or 1/4 of a bit time. A narrow high pulse is transmitted for a
zero bit when TXPOL is cleared, while a narrow low pulse is transmitted for a zero bit when TXPOL is set.

11.4.1.2 Infrared Receive Decoder

The infrared receive block converts data from the RXD pin to the receive shift register. A narrow pulse is
expected for each zero received and no pulse is expected for each one received. A narrow high pulse is
expected for a zero bit when RXPOL is cleared, while a narrow low pulse is expected for a zero bit when
RXPOL is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared
physical layer specification.

11.4.2 LIN Support

This module provides some basic support for the LIN protocol. At first this is a break detect circuitry
making it easier for the LIN software to distinguish a break character from an incoming data stream. As a
further addition is supports a collision detection at the bit level as well as cancelling pending transmissions.

11.4.3 Data Format

The SCI uses the standard NRZ mark/space data format. When Infrared is enabled, the SCI uses RZI data
format where zeroes are represented by light pulses and ones remain low. See Figure 11-15 below.
Each data character is contained in a frame that includes a start bit, eight or nine data bits, and a stop bit. Clearing the M bit in SCI control register 1 configures the SCI for 8-bit data characters. A frame with eight data bits has a total of 10 bits. Setting the M bit configures the SCI for nine-bit data characters. A frame with nine data bits has a total of 11 bits.

Table 11-14. Example of 8-Bit Data Formats

Figure 11-15. SCI Data Formats
11.4.4 Baud Rate Generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 0 to 8191 written to the SBR12:SBR0 bits determines the bus clock divisor. The SBR bits are in the SCI baud rate registers (SCIBDH and SCIBDL). The baud rate clock is synchronized with the bus clock and drives the receiver. The baud rate clock divided by 16 drives the transmitter. The receiver has an acquisition rate of 16 samples per bit time.

Baud rate generation is subject to one source of error:

- Integer division of the bus clock may not give the exact target frequency.

Table 11-16 lists some examples of achieving target baud rates with a bus clock frequency of 25 MHz.

When IREN = 0 then,

$$\text{SCI baud rate} = \frac{\text{SCI bus clock}}{16 \times \text{SCIBR}[12:0]}$$

Table 11-16. Baud Rates (Example: Bus Clock = 25 MHz)
11.4.5 Transmitter

11.4.5.1 Transmitter Character Length

The SCI transmitter can accommodate either 8-bit or 9-bit data characters. The state of the M bit in SCI control register 1 (SCICR1) determines the length of data characters. When transmitting 9-bit data, bit T8 in SCI data register high (SCIDRH) is the ninth bit (bit 8).

11.4.5.2 Character Transmission

To transmit data, the MCU writes the data bits to the SCI data registers (SCIDRH/SCIDRL), which in turn are transferred to the transmitter shift register. The transmit shift register then shifts a frame out through the TXD pin, after it has prefaced them with a start bit and appended them with a stop bit. The SCI data registers (SCIDRH and SCIDRL) are the write-only buffers between the internal data bus and the transmit shift register.
The SCI also sets a flag, the transmit data register empty flag (TDRE), every time it transfers data from the buffer (SCIDRH/L) to the transmitter shift register. The transmit driver routine may respond to this flag by writing another byte to the Transmitter buffer (SCIDRH/SCIDRL), while the shift register is still shifting out the first byte.

To initiate an SCI transmission:

1. Configure the SCI:
   a) Select a baud rate. Write this value to the SCI baud registers (SCIBDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the SCIBDH has no effect without also writing to SCIBDL.
   b) Write to SCICR1 to configure word length, parity, and other configuration bits (LOOPS,RSRC,M,WAKE,ILT,PE,PT).
   c) Enable the transmitter, interrupts, receive, and wake up as required, by writing to the SCICR2 register bits (TIE,TCIE,RIE,ILIE,TE,RE,RWU,SBK). A preamble or idle character will now be shifted out of the transmitter shift register.

2. Transmit Procedure for each byte:
   a) Poll the TDRE flag by reading the SCISR1 or responding to the TDRE interrupt. Keep in mind that the TDRE bit resets to one.
   b) If the TDRE flag is set, write the data to be transmitted to SCIDRH/L, where the ninth bit is written to the T8 bit in SCIDRH if the SCI is in 9-bit data format. A new transmission will not result until the TDRE flag has been cleared.

3. Repeat step 2 for each subsequent transmission.

**NOTE**

The TDRE flag is set when the shift register is loaded with the next data to be transmitted from SCIDRH/L, which happens, generally speaking, a little over half-way through the stop bit of the previous frame. Specifically, this transfer occurs 9/16ths of a bit time AFTER the start of the stop bit of the previous frame.

Writing the TE bit from 0 to a 1 automatically loads the transmit shift register with a preamble of 10 logic 1s (if M = 0) or 11 logic 1s (if M = 1). After the preamble shifts out, control logic transfers the data from the SCI data register into the transmit shift register. A logic 0 start bit automatically goes into the least significant bit position of the transmit shift register. A logic 1 stop bit goes into the most significant bit position.

Hardware supports odd or even parity. When parity is enabled, the most significant bit (MSB) of the data character is the parity bit.

The transmit data register empty flag, TDRE, in SCI status register 1 (SCISR1) becomes set when the SCI data register transfers a byte to the transmit shift register. The TDRE flag indicates that the SCI data register can accept new data from the internal data bus. If the transmit interrupt enable bit, TIE, in SCI control register 2 (SCICR2) is also set, the TDRE flag generates a transmitter interrupt request.
When the transmit shift register is not transmitting a frame, the TXD pin goes to the idle condition, logic 1. If at any time software clears the TE bit in SCI control register 2 (SCICR2), the transmitter enable signal goes low and the transmit signal goes idle.

If software clears TE while a transmission is in progress (TC = 0), the frame in the transmit shift register continues to shift out. To avoid accidentally cutting off the last frame in a message, always wait for TDRE to go high after the last frame before clearing TE.

To separate messages with preambles with minimum idle line time, use this sequence between messages:

1. Write the last byte of the first message to SCIDRH/L.
2. Wait for the TDRE flag to go high, indicating the transfer of the last frame to the transmit shift register.
3. Queue a preamble by clearing and then setting the TE bit.
4. Write the first byte of the second message to SCIDRH/L.

### 11.4.5.3 Break Characters

Writing a logic 1 to the send break bit, SBK, in SCI control register 2 (SCICR2) loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on the M bit in SCI control register 1 (SCICR1). As long as SBK is at logic 1, transmitter logic continuously loads break characters into the transmit shift register. After software clears the SBK bit, the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next frame.

The SCI recognizes a break character when there are 10 or 11 (M = 0 or M = 1) consecutive zero received. Depending if the break detect feature is enabled or not receiving a break character has these effects on SCI registers.

If the break detect feature is disabled (BKDFE = 0):

- Sets the framing error flag, FE
- Sets the receive data register full flag, RDRF
- Clears the SCI data registers (SCIDRH/L)
- May set the overrun flag, OR, noise flag, NF, parity error flag, PE, or the receiver active flag, RAF (see 3.4.4 and 3.4.5 SCI Status Register 1 and 2)

If the break detect feature is enabled (BKDFE = 1) there are two scenarios

The break is detected right from a start bit or is detected during a byte reception.

- Sets the break detect interrupt flag, BLDIF
- Does not change the data register full flag, RDRF or overrun flag OR
- Does not change the framing error flag FE, parity error flag PE.
- Does not clear the SCI data registers (SCIDRH/L)
- May set noise flag NF, or receiver active flag RAF.

1. A Break character in this context are either 10 or 11 consecutive zero received bits
Figure 11-17 shows two cases of break detect. In trace RXD_1 the break symbol starts with the start bit, while in RXD_2 the break starts in the middle of a transmission. If BRKDFE = 1, in RXD_1 case there will be no byte transferred to the receive buffer and the RDRF flag will not be modified. Also no framing error or parity error will be flagged from this transfer. In RXD_2 case, however the break signal starts later during the transmission. At the expected stop bit position the byte received so far will be transferred to the receive buffer, the receive data register full flag will be set, a framing error and if enabled and appropriate a parity error will be set. Once the break is detected the BRKdif flag will be set.

![Figure 11-17. Break Detection if BRKDFE = 1 (M = 0)](image)

### 11.4.5.4 Idle Characters

An idle character (or preamble) contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on the M bit in SCI control register 1 (SCICR1). The preamble is a synchronizing idle character that begins the first transmission initiated after writing the TE bit from 0 to 1.

If the TE bit is cleared during a transmission, the TXD pin becomes idle after completion of the transmission in progress. Clearing and then setting the TE bit during a transmission queues an idle character to be sent after the frame currently being transmitted.

**NOTE**

When queueing an idle character, return the TE bit to logic 1 before the stop bit of the current frame shifts out through the TXD pin. Setting TE after the stop bit appears on TXD causes data previously written to the SCI data register to be lost. Toggle the TE bit for a queued idle character while the TDRE flag is set and immediately before writing the next byte to the SCI data register.

If the TE bit is clear and the transmission is complete, the SCI is not the master of the TXD pin.
11.4.5.5 LIN Transmit Collision Detection

This module allows to check for collisions on the LIN bus.

If the bit error circuit is enabled (BERRM[1:0] = 0:1 or = 1:0), the error detect circuit will compare the transmitted and the received data stream at a point in time and flag any mismatch. The timing checks run when transmitter is active (not idle). As soon as a mismatch between the transmitted data and the received data is detected the following happens:

- The next bit transmitted will have a high level (TXPOL = 0) or low level (TXPOL = 1)
- The transmission is aborted and the byte in transmit buffer is discarded.
- The transmit data register empty and the transmission complete flag will be set
- The bit error interrupt flag, BERRIF, will be set.
- No further transmissions will take place until the BERRIF is cleared.

If the bit error detect feature is disabled, the bit error interrupt flag is cleared.

**NOTE**

The RXPOL and TXPOL bit should be set the same when transmission collision detect feature is enabled, otherwise the bit error interrupt flag may be set incorrectly.

S12P-Family Reference Manual, Rev. 1.13
11.4.6 Receiver

11.4.6.1 Receiver Character Length

The SCI receiver can accommodate either 8-bit or 9-bit data characters. The state of the M bit in SCI control register 1 (SCICR1) determines the length of data characters. When receiving 9-bit data, bit R8 in SCI data register high (SCIDRH) is the ninth bit (bit 8).

11.4.6.2 Character Reception

During an SCI reception, the receive shift register shifts a frame in from the RXD pin. The SCI data register is the read-only buffer between the internal data bus and the receive shift register.

After a complete frame shifts into the receive shift register, the data portion of the frame transfers to the SCI data register. The receive data register full flag, RDRF, in SCI status register 1 (SCISR1) becomes set,
indicating that the received byte can be read. If the receive interrupt enable bit, RIE, in SCI control register 2 (SCICR2) is also set, the RDRF flag generates an RDRF interrupt request.

### 11.4.6.3 Data Sampling

The RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock (see Figure 11-21) is re-synchronized:

- After every start bit
- After the receiver detects a data bit change from logic 1 to logic 0 (after the majority of data bit samples at RT8, RT9, and RT10 returns a valid logic 1 and the majority of the next RT8, RT9, and RT10 samples returns a valid logic 0)

To locate the start bit, data recovery logic does an asynchronous search for a logic 0 preceded by three logic 1s. When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

![Figure 11-21. Receiver Data Sampling](image)

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT5, and RT7. Figure 11-17 summarizes the results of the start bit verification samples.

<table>
<thead>
<tr>
<th>RT3, RT5, and RT7 Samples</th>
<th>Start Bit Verification</th>
<th>Noise Flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>Yes</td>
<td>0</td>
</tr>
<tr>
<td>001</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>010</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>

<td>0</td>
</tr>
<tr>
<td>110</td>
<td>No</td>
<td>0</td>
</tr>
<tr>
<td>111</td>
<td>No</td>
<td>0</td>
</tr>
</tbody>
</table>

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

S12P-Family Reference Manual, Rev. 1.13
To determine the value of a data bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. Table 11-18 summarizes the results of the data bit samples.

### Table 11-18. Data Bit Recovery

<table>

**NOTE**

The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (NF) is set and the receiver assumes that the bit is a start bit (logic 0).

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. Table 11-19 summarizes the results of the stop bit samples.

In Figure 11-22 the verification samples RT3 and RT5 determine that the first low detected was noise and not the beginning of a start bit. The RT clock is reset and the start bit search begins again. The noise flag is not set because the noise occurred before the start bit was found.
In Figure 11-23, verification sample at RT3 is high. The RT3 sample sets the noise flag. Although the perceived bit time is misaligned, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

In Figure 11-24, a large burst of noise is perceived as the beginning of a start bit, although the test sample at RT5 is high. The RT5 sample sets the noise flag. Although this is a worst-case misalignment of perceived bit time, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.
Figure 11-24 shows the effect of noise early in the start bit time. Although this noise does not affect proper synchronization with the start bit time, it does set the noise flag.

Figure 11-25 shows a burst of noise near the beginning of the start bit that resets the RT clock. The sample after the reset is low but is not preceded by three high samples that would qualify as a falling edge. Depending on the timing of the start bit search and on the data, the frame may be missed entirely or it may set the framing error flag.
In Figure 11-27, a noise burst makes the majority of data samples RT8, RT9, and RT10 high. This sets the noise flag but does not reset the RT clock. In start bits only, the RT8, RT9, and RT10 data samples are ignored.

11.4.6.4 Framing Errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming frame, it sets the framing error flag, FE, in SCI status register 1 (SCISR1). A break character also sets the FE flag because a break character has no stop bit. The FE flag is set at the same time that the RDRF flag is set.

11.4.6.5 Baud Rate Tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit. A noise error will occur if the RT8, RT9, and RT10 samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RT8, RT9, and RT10 stop bit samples are a logic zero.
As the receiver samples an incoming frame, it re-synchronizes the RT clock on any valid falling edge within the frame. Re-synchronization within frames will correct a misalignment between transmitter bit times and receiver bit times.

### 11.4.6.5.1 Slow Data Tolerance

Figure 11-28 shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

![Figure 11-28. Slow Data](image)

Let’s take RTr as receiver RT clock and RTt as transmitter RT clock.

For an 8-bit data character, it takes the receiver 9 bit times x 16 RTr cycles + 7 RTr cycles = 151 RTr cycles to start data sampling of the stop bit.

With the misaligned character shown in Figure 11-28, the receiver counts 151 RTr cycles at the point when the count of the transmitting device is 9 bit times x 16 RTt cycles = 144 RTt cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is:

\[
\frac{(151 - 144)}{151} \times 100 = 4.63\%
\]

For a 9-bit data character, it takes the receiver 10 bit times x 16 RTr cycles + 7 RTr cycles = 167 RTr cycles to start data sampling of the stop bit.

With the misaligned character shown in Figure 11-28, the receiver counts 167 RTr cycles at the point when the count of the transmitting device is 10 bit times x 16 RTt cycles = 160 RTt cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is:

\[
\frac{(167 - 160)}{167} \times 100 = 4.19\%
\]

### 11.4.6.5.2 Fast Data Tolerance

Figure 11-29 shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.
For an 8-bit data character, it takes the receiver 9 bit times x 16 RTr cycles + 10 RTr cycles = 154 RTr cycles to finish data sampling of the stop bit.

With the misaligned character shown in Figure 11-29, the receiver counts 154 RTr cycles at the point when the count of the transmitting device is 10 bit times x 16 RTt cycles = 160 RTt cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is:

\[
\frac{(160 - 154)}{160} \times 100 = 3.75\%
\]

For a 9-bit data character, it takes the receiver 10 bit times x 16 RTr cycles + 10 RTr cycles = 170 RTr cycles to finish data sampling of the stop bit.

With the misaligned character shown in Figure 11-29, the receiver counts 170 RTr cycles at the point when the count of the transmitting device is 11 bit times x 16 RTt cycles = 176 RTt cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is:

\[
\frac{(176 - 170)}{176} \times 100 = 3.40\%
\]

11.4.6.6 Receiver Wakeup

To enable the SCI to ignore transmissions intended only for other receivers in multiple-receiver systems, the receiver can be put into a standby state. Setting the receiver wakeup bit, RWU, in SCI control register 2 (SCICR2) puts the receiver into standby state during which receiver interrupts are disabled. The SCI will still load the receive data into the SCIDRH/L registers, but it will not set the RDRF flag.

The transmitting device can address messages to selected receivers by including addressing information in the initial frame or frames of each message.

The WAKE bit in SCI control register 1 (SCICR1) determines how the SCI is brought out of the standby state to process an incoming message. The WAKE bit enables either idle line wakeup or address mark wakeup.

11.4.6.6.1 Idle Input line Wakeup (WAKE = 0)

In this wakeup method, an idle condition on the RXD pin clears the RWU bit and wakes up the SCI. The initial frame or frames of every message contain addressing information. All receivers evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its RWU bit and return to the standby state.
RWU bit remains set and the receiver remains on standby until another idle character appears on the RXD pin.

Idle line wakeup requires that messages be separated by at least one idle character and that no message contains idle characters.

The idle character that wakes a receiver does not set the receiver idle bit, IDLE, or the receive data register full flag, RDRF.

The idle line type bit, ILT, determines whether the receiver begins counting logic 1s as idle character bits after the start bit or after the stop bit. ILT is in SCI control register 1 (SCICR1).

### 11.4.6.6.2 Address Mark Wakeup (WAKE = 1)

In this wakeup method, a logic 1 in the most significant bit (MSB) position of a frame clears the RWU bit and wakes up the SCI. The logic 1 in the MSB position marks a frame as an address frame that contains addressing information. All receivers evaluate the addressing information, and the receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its RWU bit and return to the standby state. The RWU bit remains set and the receiver remains on standby until another address frame appears on the RXD pin.

The logic 1 MSB of an address frame clears the receiver’s RWU bit before the stop bit is received and sets the RDRF flag.

Address mark wakeup allows messages to contain idle characters but requires that the MSB be reserved for use in address frames.

**NOTE**

With the WAKE bit clear, setting the RWU bit after the RXD pin has been idle can cause the receiver to wake up immediately.

### 11.4.7 Single-Wire Operation

Normally, the SCI uses two pins for transmitting and receiving. In single-wire operation, the RXD pin is disconnected from the SCI. The SCI uses the TXD pin for both receiving and transmitting.

![Diagram](Figure 11-30. Single-Wire Operation (LOOPS = 1, RSRC = 1))

Enable single-wire operation by setting the LOOPS bit and the receiver source bit, RSRC, in SCI control register 1 (SCICR1). Setting the LOOPS bit disables the path from the RXD pin to the receiver. Setting the RSRC bit connects the TXD pin to the receiver. Both the transmitter and receiver must be enabled (TE = 1 and RE = 1). The TXDIR bit (SCISR2[1]) determines whether the TXD pin is going to be used as an input (TXDIR = 0) or an output (TXDIR = 1) in this mode of operation.
11.4.8 Loop Operation

In loop operation the transmitter output goes to the receiver input. The RXD pin is disconnected from the SCI.

Enable loop operation by setting the LOOPS bit and clearing the RSRC bit in SCI control register 1 (SCICR1). Setting the LOOPS bit disables the path from the RXD pin to the receiver. Clearing the RSRC bit connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled (TE = 1 and RE = 1).

NOTE
In loop operation data from the transmitter is not recognized by the receiver if RXPOL and TXPOL are not the same.

11.5 Initialization/Application Information

11.5.1 Reset Initialization

See Section 11.3.2, “Register Descriptions”.

11.5.2 Modes of Operation

11.5.2.1 Run Mode

Normal mode of operation.

To initialize a SCI transmission, see Section 11.4.5.2, “Character Transmission”.

11.5.2.2 Wait Mode

SCI operation in wait mode depends on the state of the SCISWAI bit in the SCI control register 1 (SCICR1).

- If SCISWAI is clear, the SCI operates normally when the CPU is in wait mode.
- If SCISWAI is set, SCI clock generation ceases and the SCI module enters a power-conservation state when the CPU is in wait mode. Setting SCISWAI does not affect the state of the receiver enable bit, RE, or the transmitter enable bit, TE.
If SCISWAI is set, any transmission or reception in progress stops at wait mode entry. The transmission or reception resumes when either an internal or external interrupt brings the CPU out of wait mode. Exiting wait mode by reset aborts any transmission or reception in progress and resets the SCI.

11.5.2.3 Stop Mode

The SCI is inactive during stop mode for reduced power consumption. The STOP instruction does not affect the SCI register states, but the SCI bus clock will be disabled. The SCI operation resumes from where it left off after an external interrupt brings the CPU out of stop mode. Exiting stop mode by reset aborts any transmission or reception in progress and resets the SCI.

The receive input active edge detect circuit is still active in stop mode. An active edge on the receive input can be used to bring the CPU out of stop mode.

11.5.3 Interrupt Operation

This section describes the interrupt originated by the SCI block. The MCU must service the interrupt requests. Table 11-20 lists the eight interrupt sources of the SCI.

<table>
<thead>
<tr>
<th>Interrupt</th>
<th>Source</th>
<th>Local Enable</th>
<th>Description</th>

</tr>
</tbody>
</table>

11.5.3.1 Description of Interrupt Operation

The SCI only originates interrupt requests. The following is a description of how the SCI makes a request and how the MCU should acknowledge that request. The interrupt vector offset and interrupt number are chip dependent. The SCI only has a single interrupt line (SCI Interrupt Signal, active high operation) and all the following interrupts, when generated, are ORed together and issued through that port.

11.5.3.1.1 TDRE Description

The TDRE interrupt is set high by the SCI when the transmit shift register receives a byte from the SCI data register. A TDRE interrupt indicates that the transmit data register (SCIDRH/L) is empty and that a
new byte can be written to the SCIDRH/L for transmission. Clear TDRE by reading SCI status register 1 with TDRE set and then writing to SCI data register low (SCIDRL).

11.5.3.1.2 TC Description

The TC interrupt is set by the SCI when a transmission has been completed. Transmission is completed when all bits including the stop bit (if transmitted) have been shifted out and no data is queued to be transmitted. No stop bit is transmitted when sending a break character and the TC flag is set (providing there is no more data queued for transmission) when the break character has been shifted out. A TC interrupt indicates that there is no transmission in progress. TC is set high when the TDRE flag is set and no data, preamble, or break character is being transmitted. When TC is set, the TXD pin becomes idle (logic 1). Clear TC by reading SCI status register 1 (SCISR1) with TC set and then writing to SCI data register low (SCIDRL). TC is cleared automatically when data, preamble, or break is queued and ready to be sent.

11.5.3.1.3 RDRF Description

The RDRF interrupt is set when the data in the receive shift register transfers to the SCI data register. A RDRF interrupt indicates that the received data has been transferred to the SCI data register and that the byte can now be read by the MCU. The RDRF interrupt is cleared by reading the SCI status register one (SCISR1) and then reading SCI data register low (SCIDRL).

11.5.3.1.4 OR Description

The OR interrupt is set when software fails to read the SCI data register before the receive shift register receives the next frame. The newly acquired data in the shift register will be lost in this case, but the data already in the SCI data registers is not affected. The OR interrupt is cleared by reading the SCI status register one (SCISR1) and then reading SCI data register low (SCIDRL).

11.5.3.1.5 IDLE Description

The IDLE interrupt is set when 10 consecutive logic 1s (if M = 0) or 11 consecutive logic 1s (if M = 1) appear on the receiver input. Once the IDLE is cleared, a valid frame must again set the RDRF flag before an idle condition can set the IDLE flag. Clear IDLE by reading SCI status register 1 (SCISR1) with IDLE set and then reading SCI data register low (SCIDRL).

11.5.3.1.6 RXEDGIF Description

The RXEDGIF interrupt is set when an active edge (falling if RXPOL = 0, rising if RXPOL = 1) on the RXD pin is detected. Clear RXEDGIF by writing a “1” to the SCIASR1 SCI alternative status register 1.

11.5.3.1.7 BERRIF Description

The BERRIF interrupt is set when a mismatch between the transmitted and the received data in a single wire application like LIN was detected. Clear BERRIF by writing a “1” to the SCIASR1 SCI alternative status register 1. This flag is also cleared if the bit error detect feature is disabled.
11.5.3.1.8BKDIFF Description

The BKDIFF interrupt is set when a break signal was received. Clear BKDIFF by writing a “1” to the
SCIASR1 SCI alternative status register 1. This flag is also cleared if break detect feature is disabled.

11.5.4Recovery from Wait Mode

The SCI interrupt request can be used to bring the CPU out of wait mode.

11.5.5Recovery from Stop Mode

An active edge on the receive input can be used to bring the CPU out of stop mode.
Chapter 12
Serial Peripheral Interface (S12SPIV5)

12.1 Introduction
The SPI module allows a duplex, synchronous, serial communication between the MCU and peripheral devices. Software can poll the SPI status flags or the SPI operation can be interrupt driven.

12.1.1 Glossary of Terms

<table>
<thead>
<tr>
<th>SPI</th>
<th>Serial Peripheral Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>SS</td>
<td>Slave Select</td>
</tr>
<tr>
<td>SCK</td>
<td>Serial Clock</td>
</tr>
<tr>
<td>MOSI</td>
<td>Master Output, Slave Input</td>
</tr>
<tr>
<td>MISO</td>
<td>Master Input, Slave Output</td>
</tr>
<tr>
<td>MOMI</td>
<td>Master Output, Master Input</td>
</tr>
<tr>
<td>SISO</td>
<td>Slave Input, Slave Output</td>
</tr>
</tbody>
</table>

12.1.2 Features
The SPI includes these distinctive features:
- Master mode and slave mode
- Selectable 8 or 16-bit transfer width
- Bidirectional mode
- Slave select output
- Mode fault error flag with CPU interrupt capability
- Double-buffered data register
- Serial clock with programmable polarity and phase
- Control of SPI operation during wait mode

12.1.3 Modes of Operation
The SPI functions in three modes: run, wait, and stop.
- Run mode
  This is the basic mode of operation.
- Wait mode
  SPI operation in wait mode is a configurable low power mode, controlled by the SPISWAI bit located in the SPICR2 register. In wait mode, if the SPISWAI bit is clear, the SPI operates like in run mode. If the SPISWAI bit is set, the SPI goes into a power conservative state, with the SPI clock generation turned off. If the SPI is configured as a master, any transmission in progress stops, but is resumed after CPU goes into run mode. If the SPI is configured as a slave, reception and transmission of data continues, so that the slave stays synchronized to the master.
- Stop mode
  The SPI is inactive in stop mode for reduced power consumption. If the SPI is configured as a master, any transmission in progress stops, but is resumed after CPU goes into run mode. If the SPI is configured as a slave, reception and transmission of data continues, so that the slave stays synchronized to the master.

For a detailed description of operating modes, please refer to Section 12.4.7, “Low Power Mode Options”.

### 12.1.4 Block Diagram

Figure 12-1 gives an overview on the SPI architecture. The main parts of the SPI are status, control and data registers, shifter logic, baud rate generator, master/slave control logic, and port control logic.
12.2 External Signal Description

This section lists the name and description of all ports including inputs and outputs that do, or may, connect off chip. The SPI module has a total of four external pins.

12.2.1 MOSI — Master Out/Slave In Pin

This pin is used to transmit data out of the SPI module when it is configured as a master and receive data when it is configured as slave.

12.2.2 MISO — Master In/Slave Out Pin

This pin is used to transmit data out of the SPI module when it is configured as a slave and receive data when it is configured as master.
12.2.3 **SS — Slave Select Pin**

This pin is used to output the select signal from the SPI module to another peripheral with which a data transfer is to take place when it is configured as a master and it is used as an input to receive the slave select signal when the SPI is configured as slave.

12.2.4 **SCK — Serial Clock Pin**

In master mode, this is the synchronous output clock. In slave mode, this is the synchronous input clock.

12.3 **Memory Map and Register Definition**

This section provides a detailed description of address space and registers used by the SPI.

12.3.1 **Module Memory Map**

The memory map for the SPI is given in Figure 12-2. The address listed for each register is the sum of a base address and an address offset. The base address is defined at the SoC level and the address offset is defined at the module level. Reads from the reserved bits return zeros and writes to the reserved bits have no effect.

Figure 12-2. SPI Register Summary
12.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

12.3.2.1 SPI Control Register 1 (SPICR1)

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Table 12-2. SPICR1 Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 SPIE</td>
<td>SPI Interrupt Enable Bit — This bit enables SPI interrupt requests, if SPIF or MODF status flag is set. 0: SPI interrupts disabled. 1: SPI interrupts enabled.</td>
</tr>
<tr>
<td>6 SPE</td>
<td>SPI System Enable Bit — This bit enables the SPI system and dedicates the SPI port pins to SPI system functions. If SPE is cleared, SPI is disabled and forced into idle state, status bits in SPISR register are reset. 0: SPI disabled (lower power consumption). 1: SPI enabled, port pins are dedicated to SPI functions.</td>
</tr>
<tr>
<td>5 SPTIE</td>
<td>SPI Transmit Interrupt Enable — This bit enables SPI interrupt requests, if SPTEF flag is set. 0: SPTEF interrupt disabled. 1: SPTEF interrupt enabled.</td>
</tr>
<tr>
<td>4 MSTR</td>
<td>SPI Master/Slave Mode Select Bit — This bit selects whether the SPI operates in master or slave mode. Switching the SPI from master to slave or vice versa forces the SPI system into idle state. 0: SPI is in slave mode. 1: SPI is in master mode.</td>
</tr>
<tr>
<td>3 CPOL</td>
<td>SPI Clock Polarity Bit — This bit selects an inverted or non-inverted SPI clock. To transmit data between SPI modules, the SPI modules must have identical CPOL values. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0: Active-high clocks selected. In idle state SCK is low. 1: Active-low clocks selected. In idle state SCK is high.</td>
</tr>
<tr>
<td>2 CPHA</td>
<td>SPI Clock Phase Bit — This bit is used to select the SPI clock format. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0: Sampling of data occurs at odd edges (1,3,5,...) of the SCK clock. 1: Sampling of data occurs at even edges (2,4,6,...) of the SCK clock.</td>
</tr>
</tbody>
</table>

Table 12-4. SPI CR2 Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>Transfer Width — This bit is used for selecting the data transfer width. If 8-bit transfer width is selected, SPIDRL becomes the dedicated data register and SPIDRH is unused. If 16-bit transfer width is selected, SPIDRH and SPIDRL form a 16-bit data register. Please refer to Section 12.3.2.4, “SPI Status Register (SPISR)” for information about transmit/receive data handling and the interrupt flag clearing mechanism. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 8-bit Transfer Width ((n = 8)) 1 16-bit Transfer Width ((n = 16))</td>
</tr>
<tr>
<td>4</td>
<td>Mode Fault Enable Bit — This bit allows the MODF failure to be detected. If the SPI is in master mode and MODFEN is cleared, then the (SS) port pin is not used by the SPI. In slave mode, the (SS) is available only as an input regardless of the value of MODFEN. For an overview on the impact of the MODFEN bit on the (SS) port pin configuration, refer to Table 12-3. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 (SS) port pin is not used by the SPI. 1 (SS) port pin with MODF feature.</td>
</tr>
<tr>
<td>3</td>
<td>Output Enable in the Bidirectional Mode of Operation — This bit controls the MOSI and MISO output buffer of the SPI, when in bidirectional mode of operation (SPC0 is set). In master mode, this bit controls the output buffer of the MOSI port, in slave mode it controls the output buffer of the MISO port. In master mode, with SPC0 set, a change of this bit will abort a transmission in progress and force the SPI into idle state. 0 Output buffer disabled. 1 Output buffer enabled.</td>
</tr>
<tr>
<td>1</td>
<td>SPI Stop in Wait Mode Bit — This bit is used for power conservation while in wait mode. 0 SPI clock operates normally in wait mode. 1 Stop SPI clock generation when in wait mode.</td>
</tr>
<tr>
<td>0</td>
<td>Serial Pin Control Bit 0 — This bit enables bidirectional pin configurations as shown in Table 12-5. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state.</td>
</tr>
</tbody>
</table>

1. \(n\) is used later in this document as a placeholder for the selected transfer width.

12.3.2.3 SPI Baud Rate Register (SPIBR)

Read: Anytime
Write: Anytime; writes to the reserved bits have no effect

The baud rate divisor equation is as follows:

\[ \text{BaudRateDivisor} = (\text{SPPR} + 1) \cdot 2^{(\text{SPR} + 1)} \]

Eqn. 12-1

The baud rate can be calculated with the following equation:

\[ \text{Baud Rate} = \frac{\text{BusClock}}{\text{BaudRateDivisor}} \]

Eqn. 12-2

NOTE

For maximum allowed baud rates, please refer to the SPI Electrical Specification in the Electricals chapter of this data sheet.

</tbody>
</table>
| 1        | Read SPISR with SPIF == 1 then Byte Read SPIDRL<br><br>
|          | or Byte Read SPIDRH<br>
|          | or Byte Read SPIDRL<br>
|          | or Word Read (SPIDRH:SPIDRL)                               |

1. Data in SPIDRH is lost in this case.
2. SPIDRH can be read repeatedly without any effect on SPIF. SPIF Flag is cleared only by the read of SPIDRL after reading SPISR with SPIF == 1.

### Table 12-10. SPTEF Interrupt Flag Clearing Sequence

<table>
<thead>
<tr>
<th>XFRW Bit</th>
<th>SPTEF Interrupt Flag Clearing Sequence</th>
</tr>
</thead>
</table>
| 0        | Read SPISR with SPTEF == 1 then Write to SPIDRL<br><br>
| 1        | Read SPISR with SPTEF == 1 then Byte Write to SPIDRL<br>
|          | or Byte Write to SPIDRH<br>
|          | or Byte Write to SPIDRL<br>
|          | or Word Write to (SPIDRH:SPIDRL)                             |

1. Any write to SPIDRH or SPIDRL with SPTEF == 0 is effectively ignored.
2. Data in SPIDRH is undefined in this case.
3. SPIDRH can be written repeatedly without any effect on SPTEF. SPTEF Flag is cleared only by writing to SPIDRL after reading SPISR with SPTEF == 1.
12.3.2.5 SPI Data Register (SPIDR = SPIDRH:SPIDRL)

The SPI data register is both the input and output register for SPI data. A write to this register allows data to be queued and transmitted. For an SPI configured as a master, queued data is transmitted immediately after the previous transmission has completed. The SPI transmitter empty flag SPTEF in the SPISR register indicates when the SPI data register is ready to accept new data. Received data in the SPIDR is valid when SPIF is set.

If SPIF is cleared and data has been received, the received data is transferred from the receive shift register to the SPIDR and SPIF is set.

If SPIF is set and not serviced, and a second data value has been received, the second received data is kept as valid data in the receive shift register until the start of another transmission. The data in the SPIDR does not change.

If SPIF is set and valid data is in the receive shift register, and SPIF is serviced before the start of a third transmission, the data in the receive shift register is transferred into the SPIDR and SPIF remains set (see Figure 12-9).

If SPIF is set and valid data is in the receive shift register, and SPIF is serviced after the start of a third transmission, the data in the receive shift register has become invalid and is not transferred into the SPIDR (see Figure 12-10).
12.4 Functional Description

The SPI module allows a duplex, synchronous, serial communication between the MCU and peripheral devices. Software can poll the SPI status flags or SPI operation can be interrupt driven.

The SPI system is enabled by setting the SPI enable (SPE) bit in SPI control register 1. While SPE is set, the four associated SPI port pins are dedicated to the SPI function as:

- Slave select (SS)
- Serial clock (SCK)
- Master out/slave in (MOSI)
- Master in/slave out (MISO)
The main element of the SPI system is the SPI data register. The n-bit\(^1\) data register in the master and the n-bit\(^1\) data register in the slave are linked by the MOSI and MISO pins to form a distributed 2n-bit\(^1\) register. When a data transfer operation is performed, this 2n-bit\(^1\) register is serially shifted n\(^1\) bit positions by the S-clock from the master, so data is exchanged between the master and the slave. Data written to the master SPI data register becomes the output data for the slave, and data read from the master SPI data register after a transfer operation is the input data from the slave.

A read of SPI SR with SPTEF = 1 followed by a write to SPI DR puts data into the transmit data register. When a transfer is complete and SPIF is cleared, received data is moved into the receive data register. This data register acts as the SPI receive data register for reads and as the SPI transmit data register for writes. A common SPI data register address is shared for reading data from the read data buffer and for writing data to the transmit data register.

The clock phase control bit (CPHA) and a clock polarity control bit (CPOL) in the SPI control register 1 (SPI CR1) select one of four possible clock formats to be used by the SPI system. The CPOL bit simply selects a non-inverted or inverted clock. The CPHA bit is used to accommodate two fundamentally different protocols by sampling data on odd numbered SCK edges or on even numbered SCK edges (see Section 12.4.3, “Transmission Formats”).

The SPI can be configured to operate as a master or as a slave. When the MSTR bit in SPI control register 1 is set, master mode is selected, when the MSTR bit is clear, slave mode is selected.

**NOTE**

A change of CPOL or MSTR bit while there is a received byte pending in the receive shift register will destroy the received byte and must be avoided.

### 12.4.1 Master Mode

The SPI operates in master mode when the MSTR bit is set. Only a master SPI module can initiate transmissions. A transmission begins by writing to the master SPI data register. If the shift register is empty, data immediately transfers to the shift register. Data begins shifting out on the MOSI pin under the control of the serial clock.

- **Serial clock**
  The SPR2, SPR1, and SPR0 baud rate selection bits, in conjunction with the SPPR2, SPPR1, and SPPR0 baud rate preselection bits in the SPI baud rate register, control the baud rate generator and determine the speed of the transmission. The SCK pin is the SPI clock output. Through the SCK pin, the baud rate generator of the master controls the shift register of the slave peripheral.

- **MOSI, MISO pin**
  In master mode, the function of the serial data output pin (MOSI) and the serial data input pin (MISO) is determined by the SPC0 and BIDIROE control bits.

- **SS pin**
  If MODFEN and SSOE are set, the SS pin is configured as slave select output. The SS output becomes low during each transmission and is high when the SPI is in idle state.
  
  If MODFEN is set and SSOE is cleared, the SS pin is configured as input for detecting mode fault error. If the SS input becomes low this indicates a mode fault error where another master tries to...

---

1. n depends on the selected transfer width, please refer to Section 12.3.2.2, "SPI Control Register 2 (SPI CR2)"

---

**S12P-Family Reference Manual, Rev. 1.13**

Freescale Semiconductor
drive the MOSI and SCK lines. In this case, the SPI immediately switches to slave mode, by clearing the MSTR bit and also disables the slave output buffer MISO (or SISO in bidirectional mode). So the result is that all outputs are disabled and SCK, MOSI, and MISO are inputs. If a transmission is in progress when the mode fault occurs, the transmission is aborted and the SPI is forced into idle state.

This mode fault error also sets the mode fault (MODF) flag in the SPI status register (SPISR). If the SPI interrupt enable bit (SPIE) is set when the MODF flag becomes set, then an SPI interrupt sequence is also requested.

When a write to the SPI data register in the master occurs, there is a half SCK-cycle delay. After the delay, SCK is started within the master. The rest of the transfer operation differs slightly, depending on the clock format specified by the SPI clock phase bit, CPHA, in SPI control register 1 (see Section 12.4.3, “Transmission Formats”).

NOTE
A change of the bits CPOL, CPHA, SS0E, LSBFE, XFRW, MODFEN, SPC0, or BIDIROE with SPC0 set, SPPR2-SPPR0 and SPR2-SPR0 in master mode will abort a transmission in progress and force the SPI into idle state. The remote slave cannot detect this, therefore the master must ensure that the remote slave is returned to idle state.

12.4.2 Slave Mode
The SPI operates in slave mode when the MSTR bit in SPI control register 1 is clear.

• Serial clock
  In slave mode, SCK is the SPI clock input from the master.

• MISO, MOSI pin
  In slave mode, the function of the serial data output pin (MISO) and serial data input pin (MOSI) is determined by the SPC0 bit and BIDIROE bit in SPI control register 2.

• SS pin
  The SS pin is the slave select input. Before a data transmission occurs, the SS pin of the slave SPI must be low. SS must remain low until the transmission is complete. If SS goes high, the SPI is forced into idle state.
  The SS input also controls the serial data output pin, if SS is high (not selected), the serial data output pin is high impedance, and, if SS is low, the first bit in the SPI data register is driven out of the serial data output pin. Also, if the slave is not selected (SS is high), then the SCK input is ignored and no internal shifting of the SPI shift register occurs.

Although the SPI is capable of duplex operation, some SPI peripherals are capable of only receiving SPI data in a slave mode. For these simpler devices, there is no serial data out pin.

NOTE
When peripherals with duplex capability are used, take care not to simultaneously enable two receivers whose serial outputs drive the same system slave’s serial data output line.
As long as no more than one slave device drives the system slave’s serial data output line, it is possible for several slaves to receive the same transmission from a master, although the master would not receive return information from all of the receiving slaves.

If the CPHA bit in SPI control register 1 is clear, odd numbered edges on the SCK input cause the data at the serial data input pin to be latched. Even numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

If the CPHA bit is set, even numbered edges on the SCK input cause the data at the serial data input pin to be latched. Odd numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

When CPHA is set, the first edge is used to get the first data bit onto the serial data output pin. When CPHA is clear and the SS input is low (slave selected), the first bit of the SPI data is driven out of the serial data output pin. After the \( n \)th shift, the transfer is considered complete and the received data is transferred into the SPI data register. To indicate transfer is complete, the SPIF flag in the SPI status register is set.

**NOTE**

A change of the bits CPOL, CPHA, SSOE, LSBFE, MODFEN, SPC0, or BIDIROE with SPC0 set in slave mode will corrupt a transmission in progress and must be avoided.

### 12.4.3 Transmission Formats

During an SPI transmission, data is transmitted (shifted out serially) and received (shifted in serially) simultaneously. The serial clock (SCK) synchronizes shifting and sampling of the information on the two serial data lines. A slave select line allows selection of an individual slave SPI device; slave devices that are not selected do not interfere with SPI bus activities. Optionally, on a master SPI device, the slave select line can be used to indicate multiple-master bus contention.

![Figure 12-11. Master/Slave Transfer Block Diagram](image)

#### 12.4.3.1 Clock Phase and Polarity Controls

Using two bits in the SPI control register 1, software selects one of four combinations of serial clock phase and polarity.

1. \( n \) depends on the selected transfer width, please refer to Section 12.3.2.2, "SPI Control Register 2 (SPICR2)"

---

**S12P-Family Reference Manual, Rev. 1.13**

Freescale Semiconductor
The CPOL clock polarity control bit specifies an active high or low clock and has no significant effect on the transmission format.

The CPHA clock phase control bit selects one of two fundamentally different transmission formats.

Clock phase and polarity should be identical for the master SPI device and the communicating slave device. In some cases, the phase and polarity are changed between transmissions to allow a master device to communicate with peripheral slaves having different requirements.

12.4.3.2 CPHA = 0 Transfer Format

The first edge on the SCK line is used to clock the first data bit of the slave into the master and the first data bit of the master into the slave. In some peripherals, the first bit of the slave’s data is available at the slave’s data out pin as soon as the slave is selected. In this format, the first SCK edge is issued a half cycle after SS has become low.

A half SCK cycle later, the second edge appears on the SCK line. When this second edge occurs, the value previously latched from the serial data input pin is shifted into the LSB or MSB of the shift register, depending on LSBFE bit.

After this second edge, the next bit of the SPI master data is transmitted out of the serial data output pin of the master to the serial input pin on the slave. This process continues for a total of 16 edges on the SCK line, with data being latched on odd numbered edges and shifted on even numbered edges.

Data reception is double buffered. Data is shifted serially into the SPI shift register during the transfer and is transferred to the parallel SPI data register after the last bit is shifted in.

After $2n^1$ (last) SCK edges:

- Data that was previously in the master SPI data register should now be in the slave data register and the data that was in the slave data register should be in the master.
- The SPIF flag in the SPI status register is set, indicating that the transfer is complete.

Figure 12-12 is a timing diagram of an SPI transfer where CPHA = 0. SCK waveforms are shown for CPOL = 0 and CPOL = 1. The diagram may be interpreted as a master or slave timing diagram because the SCK, MISO, and MOSI pins are connected directly between the master and the slave. The MISO signal is the output from the slave and the MOSI signal is the output from the master. The SS pin of the master must be either high or reconfigured as a general-purpose output not affecting the SPI.

1. n depends on the selected transfer width, please refer to Section 12.3.2.2, "SPI Control Register 2 (SPICR2)"

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor
Figure 12-12. SPI Clock Format 0 (CPHA = 0), with 8-bit Transfer Width selected (XFRW = 0)
Serial Peripheral Interface (S12SPIV5)

In slave mode, if the SS line is not deasserted between the successive transmissions then the content of the SPI data register is not transmitted; instead the last received data is transmitted. If the SS line is deasserted for at least minimum idle time (half SCK cycle) between successive transmissions, then the content of the SPI data register is transmitted.

In master mode, with slave select output enabled the SS line is always deasserted and reasserted between successive transfers for at least minimum idle time.

### 12.4.3.3 CPHA = 1 Transfer Format

Some peripherals require the first SCK edge before the first data bit becomes available at the data out pin, the second edge clocks data into the system. In this format, the first SCK edge is issued by setting the CPHA bit at the beginning of the n1-cycle transfer operation.

The first edge of SCK occurs immediately after the half SCK clock cycle synchronization delay. This first edge commands the slave to transfer its first data bit to the serial data input pin of the master.

A half SCK cycle later, the second edge appears on the SCK pin. This is the latching edge for both the master and slave.

1. n depends on the selected transfer width, please refer to Section 12.3.2.2, *SPI Control Register 2 (SPICR2)*

---

**Freescale Semiconductor**

S12P-Family Reference Manual, Rev. 1.13

417
When the third edge occurs, the value previously latched from the serial data input pin is shifted into the LSB or MSB of the SPI shift register, depending on LSBFE bit. After this edge, the next bit of the master data is coupled out of the serial data output pin of the master to the serial input pin on the slave.

This process continues for a total of \( n \) edges on the SCK line with data being latched on even numbered edges and shifting taking place on odd numbered edges.

Data reception is double buffered, data is serially shifted into the SPI shift register during the transfer and is transferred to the parallel SPI data register after the last bit is shifted in.

After \( 2n \) SCK edges:
- Data that was previously in the SPI data register of the master is now in the data register of the slave, and data that was in the data register of the slave is in the master.
- The SPIF flag bit in SPIISR is set indicating that the transfer is complete.

Figure 12-14 shows two clocking variations for CPHA = 1. The diagram may be interpreted as a master or slave timing diagram because the SCK, MISO, and MOSI pins are connected directly between the master and the slave. The MISO signal is the output from the slave, and the MOSI signal is the output from the master. The SS line is the slave select input to the slave. The SS pin of the master must be either high or reconfigured as a general-purpose output not affecting the SPI.

![Figure 12-14. SPI Clock Format 1 (CPHA = 1), with 8-Bit Transfer Width selected (XFRW = 0)](image)
The SS line can remain active low between successive transfers (can be tied low at all times). This format is sometimes preferred in systems having a single fixed master and a single slave that drive the MISO data line.

- **Back-to-back transfers in master mode**
  - In master mode, if a transmission has completed and new data is available in the SPI data register, this data is sent out immediately without a trailing and minimum idle time.

The SPI interrupt request flag (SPIF) is common to both the master and slave modes. SPIF gets set one half SCK cycle after the last SCK edge.

### 12.4.4 SPI Baud Rate Generation

Baud rate generation consists of a series of divider stages. Six bits in the SPI baud rate register (SPPR2, SPPR1, SPPR0, SPR2, SPR1, and SPR0) determine the divisor to the SPI module clock which results in the SPI baud rate.

The SPI clock rate is determined by the product of the value in the baud rate preselection bits (SPPR2–SPPR0) and the value in the baud rate selection bits (SPR2–SPR0). The module clock divisor equation is shown in Equation 12-3.

$$\text{BaudRateDivisor} = (\text{SPPR} + 1) \times 2^{(\text{SPR} + 1)}$$

*Eqn. 12-3*

---

**Figure 12-15. SPI Clock Format 1 (CPHA = 1), with 16-Bit Transfer Width selected (XFRW = 1)**
When all bits are clear (the default condition), the SPI module clock is divided by 2. When the selection bits (SPR2–SPR0) are 001 and the preselection bits (SPPR2–SPPR0) are 000, the module clock divisor becomes 4. When the selection bits are 010, the module clock divisor becomes 8, etc.

When the preselection bits are 001, the divisor determined by the selection bits is multiplied by 2. When the preselection bits are 010, the divisor is multiplied by 3, etc. See Table 12-7 for baud rate calculations for all bit conditions, based on a 25 MHz bus clock. The two sets of selects allows the clock to be divided by a non-power of two to achieve other baud rates such as divide by 6, divide by 10, etc.

The baud rate generator is activated only when the SPI is in master mode and a serial transfer is taking place. In the other cases, the divider is disabled to decrease IDD current.

**NOTE**

For maximum allowed baud rates, please refer to the SPI Electrical Specification in the Electricals chapter of this data sheet.

### 12.4.5 Special Features

#### 12.4.5.1 SS Output

The SS output feature automatically drives the SS pin low during transmission to select external devices and drives it high during idle to deselect external devices. When SS output is selected, the SS output pin is connected to the SS input pin of the external device.

The SS output is available only in master mode during normal SPI operation by asserting SSOE and MODFEN bit as shown in Table 12-3.

The mode fault feature is disabled while SS output is enabled.

**NOTE**

Care must be taken when using the SS output feature in a multimaster system because the mode fault feature is not available for detecting system errors between masters.

#### 12.4.5.2 Bidirectional Mode (MOMI or SISO)

The bidirectional mode is selected when the SPC0 bit is set in SPI control register 2 (see Table 12-11). In this mode, the SPI uses only one serial data pin for the interface with external device(s). The MSTR bit decides which pin to use. The MOSI pin becomes the serial data I/O (MOMI) pin for the master mode, and the MISO pin becomes serial data I/O (SISO) pin for the slave mode. The MISO pin in master mode and MOSI pin in slave mode are not used by the SPI.
The direction of each serial I/O pin depends on the BIDIROE bit. If the pin is configured as an output, serial data from the shift register is driven out on the pin. The same pin is also the serial input to the shift register.

- The SCK is output for the master mode and input for the slave mode.
- The SS is the input or output for the master mode, and it is always the input for the slave mode.
- The bidirectional mode does not affect SCK and SS functions.

**NOTE**

In bidirectional master mode, with mode fault enabled, both data pins MISO and MOSI can be occupied by the SPI, though MOSI is normally used for transmissions in bidirectional mode and MISO is not used by the SPI. If a mode fault occurs, the SPI is automatically switched to slave mode. In this case MISO becomes occupied by the SPI and MOSI is not used. This must be considered, if the MISO pin is used for another purpose.

### 12.4.6 Error Conditions

The SPI has one error condition:

- Mode fault error

#### 12.4.6.1 Mode Fault Error

If the SS input becomes low while the SPI is configured as a master, it indicates a system error where more than one master may be trying to drive the MOSI and SCK lines simultaneously. This condition is not permitted in normal operation, the MODF bit in the SPI status register is set automatically, provided the MODFEN bit is set.

In the special case where the SPI is in master mode and MODFEN bit is cleared, the SS pin is not used by the SPI. In this special case, the mode fault error function is inhibited and MODF remains cleared. In case...
the SPI system is configured as a slave, the SS pin is a dedicated input pin. Mode fault error doesn’t occur in slave mode.

If a mode fault error occurs, the SPI is switched to slave mode, with the exception that the slave output buffer is disabled. So SCK, MISO, and MOSI pins are forced to be high impedance inputs to avoid any possibility of conflict with another output driver. A transmission in progress is aborted and the SPI is forced into idle state.

If the mode fault error occurs in the bidirectional mode for a SPI system configured in master mode, output enable of the MOMI (MOSI in bidirectional mode) is cleared if it was set. No mode fault error occurs in the bidirectional mode for SPI system configured in slave mode.

The mode fault flag is cleared automatically by a read of the SPI status register (with MODF set) followed by a write to SPI control register 1. If the mode fault flag is cleared, the SPI becomes a normal master or slave again.

**NOTE**

If a mode fault error occurs and a received data byte is pending in the receive shift register, this data byte will be lost.

### 12.4.7 Low Power Mode Options

#### 12.4.7.1 SPI in Run Mode

In run mode with the SPI system enable (SPE) bit in the SPI control register clear, the SPI system is in a low-power, disabled state. SPI registers remain accessible, but clocks to the core of this module are disabled.

#### 12.4.7.2 SPI in Wait Mode

SPI operation in wait mode depends upon the state of the SPISWAI bit in SPI control register 2.

- If SPISWAI is clear, the SPI operates normally when the CPU is in wait mode
- If SPISWAI is set, SPI clock generation ceases and the SPI module enters a power conservation state when the CPU is in wait mode.
  - If SPISWAI is set and the SPI is configured for master, any transmission and reception in progress stops at wait mode entry. The transmission and reception resumes when the SPI exits wait mode.
  - If SPISWAI is set and the SPI is configured as a slave, any transmission and reception in progress continues if the SCK continues to be driven from the master. This keeps the slave synchronized to the master and the SCK.

If the master transmits several bytes while the slave is in wait mode, the slave will continue to send out bytes consistent with the operation mode at the start of wait mode (i.e., if the slave is currently sending its SPIDR to the master, it will continue to send the same byte. Else if the slave is currently sending the last received byte from the master, it will continue to send each previous master byte).
NOTE
Care must be taken when expecting data from a master while the slave is in wait or stop mode. Even though the shift register will continue to operate, the rest of the SPI is shut down (i.e., a SPIF interrupt will not be generated until exiting stop or wait mode). Also, the byte from the shift register will not be copied into the SPIDR register until after the slave SPI has exited wait or stop mode. In slave mode, a received byte pending in the receive shift register will be lost when entering wait or stop mode. An SPIF flag and SPIDR copy is generated only if wait mode is entered or exited during a transmission. If the slave enters wait mode in idle mode and exits wait mode in idle mode, neither a SPIF nor a SPIDR copy will occur.

12.4.7.3 SPI in Stop Mode
Stop mode is dependent on the system. The SPI enters stop mode when the module clock is disabled (held high or low). If the SPI is in master mode and exchanging data when the CPU enters stop mode, the transmission is frozen until the CPU exits stop mode. After stop, data to and from the external SPI is exchanged correctly. In slave mode, the SPI will stay synchronized with the master.

The stop mode is not dependent on the SPISWAI bit.

12.4.7.4 Reset
The reset values of registers and signals are described in Section 12.3, “Memory Map and Register Definition”, which details the registers and their bit fields.

- If a data transmission occurs in slave mode after reset without a write to SPIDR, it will transmit garbage, or the data last received from the master before the reset.
- Reading from the SPIDR after reset will always read zeros.

12.4.7.5 Interrupts
The SPI only originates interrupt requests when SPI is enabled (SPE bit in SPICR1 set). The following is a description of how the SPI makes a request and how the MCU should acknowledge that request. The interrupt vector offset and interrupt priority are chip dependent.

The interrupt flags MODF, SPIF, and SPTEF are logically ORed to generate an interrupt request.

12.4.7.5.1 MODF
MODF occurs when the master detects an error on the SS pin. The master SPI must be configured for the MODF feature (see Table 12-3). After MODF is set, the current transfer is aborted and the following bit is changed:

- MSTR = 0, The master bit in SPICR1 resets.

The MODF interrupt is reflected in the status register MODF flag. Clearing the flag will also clear the interrupt. This interrupt will stay active while the MODF flag is set. MODF has an automatic clearing process which is described in Section 12.3.2.4, “SPI Status Register (SPISR)”.

S12P-Family Reference Manual, Rev. 1.13
Freescale Semiconductor 423
12.4.7.5.2 SPIF

SPIF occurs when new data has been received and copied to the SPI data register. After SPIF is set, it does not clear until it is serviced. SPIF has an automatic clearing process, which is described in Section 12.3.2.4, “SPI Status Register (SPISR)”. 

12.4.7.5.3 SPTEF

SPTEF occurs when the SPI data register is ready to accept new data. After SPTEF is set, it does not clear until it is serviced. SPTEF has an automatic clearing process, which is described in Section 12.3.2.4, “SPI Status Register (SPISR)”.

13.1 Introduction

The FTMRC128K1 module implements the following:

- 128 Kbytes of P-Flash (Program Flash) memory
- 4 Kbytes of D-Flash (Data Flash) memory

The Flash memory is ideal for single-supply applications allowing for field reprogramming without requiring external high voltage sources for program or erase operations. The Flash module includes a memory controller that executes commands to modify Flash memory contents. The user interface to the memory controller consists of the indexed Flash Common Command Object (FCCOB) register which is written to with the command, global address, data, and any required command parameters. The memory controller must complete the execution of a command before the FCCOB register can be written to with a new command.
CAUTION

A Flash word or phrase must be in the erased state before being programmed. Cumulative programming of bits within a Flash word or phrase is not allowed.

The Flash memory may be read as bytes, aligned words, or misaligned words. Read access time is one bus cycle for bytes and aligned words, and two bus cycles for misaligned words. For Flash memory, an erased bit reads 1 and a programmed bit reads 0.

It is possible to read from P-Flash memory while some commands are executing on D-Flash memory. It is not possible to read from D-Flash memory while a command is executing on P-Flash memory. Simultaneous P-Flash and D-Flash operations are discussed in Section 13.4.4.

Both P-Flash and D-Flash memories are implemented with Error Correction Codes (ECC) that can resolve single bit faults and detect double bit faults. For P-Flash memory, the ECC implementation requires that programming be done on an aligned 8 byte basis (a Flash phrase). Since P-Flash memory is always read by half-phrase, only one single bit fault in an aligned 4 byte half-phrase containing the byte or word accessed will be corrected.

13.1.1 Glossary

Command Write Sequence — An MCU instruction sequence to execute built-in algorithms (including program and erase) on the Flash memory.

D-Flash Memory — The D-Flash memory constitutes the nonvolatile memory store for data.

D-Flash Sector — The D-Flash sector is the smallest portion of the D-Flash memory that can be erased. The D-Flash sector consists of four 64 byte rows for a total of 256 bytes.

NVM Command Mode — An NVM mode using the CPU to setup the FCCOB register to pass parameters required for Flash command execution.

Phrase — An aligned group of four 16-bit words within the P-Flash memory. Each phrase includes two sets of aligned double words with each set including 7 ECC bits for single bit fault correction and double bit fault detection within each double word.

P-Flash Memory — The P-Flash memory constitutes the main nonvolatile memory store for applications.

P-Flash Sector — The P-Flash sector is the smallest portion of the P-Flash memory that can be erased. Each P-Flash sector contains 512 bytes.

Program IFR — Nonvolatile information register located in the P-Flash block that contains the Device ID, Version ID, and the Program Once field.
13.1.2 Features

13.1.2.1 P-Flash Features

- 128 Kbytes of P-Flash memory composed of one 128 Kbyte Flash block divided into 256 sectors of 512 bytes
- Single bit fault correction and double bit fault detection within a 32-bit double word during read operations
- Automated program and erase algorithm with verify and generation of ECC parity bits
- Fast sector erase and phrase program operation
- Ability to read the P-Flash memory while programming a word in the D-Flash memory
- Flexible protection scheme to prevent accidental program or erase of P-Flash memory

13.1.2.2 D-Flash Features

- 4 Kbytes of D-Flash memory composed of one 4 Kbyte Flash block divided into 16 sectors of 256 bytes
- Single bit fault correction and double bit fault detection within a word during read operations
- Automated program and erase algorithm with verify and generation of ECC parity bits
- Fast sector erase and word program operation
- Protection scheme to prevent accidental program or erase of D-Flash memory
- Ability to program up to four words in a burst sequence

13.1.2.3 Other Flash Module Features

- No external high-voltage power supply required for Flash memory program and erase operations
- Interrupt generation on Flash command completion and Flash error detection
- Security mechanism to prevent unauthorized access to the Flash memory

13.1.3 Block Diagram

The block diagram of the Flash module is shown in Figure 13-1.
13.2 External Signal Description

The Flash module contains no signals that connect off-chip.
13.3 Memory Map and Registers

This section describes the memory map and registers for the Flash module. Read data from unimplemented memory space in the Flash module is undefined. Write access to unimplemented or reserved memory space in the Flash module will be ignored by the Flash module.

13.3.1 Module Memory Map

The S12 architecture places the P-Flash memory between global addresses 0x2_0000 and 0x3_FFFF as shown in Table 13-2. The P-Flash memory map is shown in Figure 13-2.

<table>

<td>P-Flash Block Contains Flash Configuration Field (see Table 13-3)</td>
</tr>
</tbody>
</table>

The FPROT register, described in Section 13.3.2.9, can be set to protect regions in the Flash memory from accidental program or erase. Three separate memory regions, one growing upward from global address 0x3_8000 in the Flash memory (called the lower region), one growing downward from global address 0x3_FFFF in the Flash memory (called the higher region), and the remaining addresses in the Flash memory, can be activated for protection. The Flash memory addresses covered by these protectable regions are shown in the P-Flash memory map. The higher address region is mainly targeted to hold the boot loader code since it covers the vector space. Default protection settings as well as security information that allows the MCU to restrict access to the Flash module are stored in the Flash configuration field as described in Table 13-3.

13.3.2 Register Descriptions

The Flash module contains a set of 20 control and status registers located between Flash module base + 0x0000 and 0x0013. A summary of the Flash module registers is given in Figure 13-4 with detailed descriptions in the following subsections.

CAUTION

Writes to any Flash register must be avoided while a Flash command is active (CCIF=0) to prevent corruption of Flash register contents and adversely affect Memory Controller behavior.

= Unimplemented or Reserved
All bits in the FCLKDIV register are readable, bit 7 is not writable, bit 6 is write-once-hi and controls the writability of the FDIV field.

**CAUTION**

The FCLKDIV register must never be written to while a Flash command is executing (CCIF=0). The FCLKDIV register is writable during the Flash reset sequence even though CCIF is clear.

### Table 13-6. FCLKDIV Field Descriptions

<td>32.6</td>
</tr>
</tbody>
</table>

1. BUSCLK is Greater Than this value.
2. BUSCLK is Less Than or Equal to this value.

All bits in the FSEC register are readable but not writable.

During the reset sequence, the FSEC register is loaded with the contents of the Flash security byte in the Flash configuration field at global address 0x3_FF0F located in P-Flash memory (see Table 13-3) as indicated by reset condition F in Figure 13-6. If a double bit fault is detected while reading the P-Flash
phrase containing the Flash security byte during the reset sequence, all bits in the FSEC register will be set to leave the Flash module in a secured state with backdoor key access disabled.

</tbody>
</table>

1. Preferred SEC state to set MCU to secured state.

The security function in the Flash module is described in **Section 13.5.**

### 13.3.2.3 Flash CCOB Index Register (FCCOBIX)

The FCCOBIX register is used to index the FCCOB register for Flash memory operations.

The FCCOBIX bits are readable and writable while remaining bits read 0 and are not writable.
13.3.2.4 Flash Reserved0 Register (FRSV0)

This Flash register is reserved for factory testing.

All bits in the FRSV0 register read 0 and are not writable.

13.3.2.5 Flash Configuration Register (FCNFG)

The FCNFG register enables the Flash command complete interrupt and forces ECC faults on Flash array read access from the CPU.

CCIE, IGNSF, FDFD, and FSFD bits are readable and writable while remaining bits read 0 and are not writable.
### Table 13-12. FCNFG Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 CCIE | **Command Complete Interrupt Enable** — The CCIE bit controls interrupt generation when a Flash command has completed.  
  0 Command complete interrupt disabled  
  1 An interrupt will be requested whenever the CCIF flag in the FSTAT register is set (see Section 13.3.2.7) |
| 4 IGNSF | **Ignore Single Bit Fault** — The IGNSF controls single bit fault reporting in the FERSTAT register (see Section 13.3.2.8).  
  0 All single bit faults detected during array reads are reported  
  1 Single bit faults detected during array reads are not reported and the single bit fault interrupt will not be generated |
| 1 FDFD | **Force Double Bit Fault Detect** — The FDFD bit allows the user to simulate a double bit fault during Flash array read operations and check the associated interrupt routine. The FDFD bit is cleared by writing a 0 to FDFD. The FECCR registers will not be updated during the Flash array read operation with FDFD set unless an actual double bit fault is detected.  
  0 Flash array read operations will set the DFDIF flag in the FERSTAT register only if a double bit fault is detected  
  1 Any Flash array read operation will force the DFDIF flag in the FERSTAT register to be set (see Section 13.3.2.7) and an interrupt will be generated as long as the DFDIE interrupt enable in the FERCNFG register is set (see Section 13.3.2.6) |
| 0 FSFD | **Force Single Bit Fault Detect** — The FSFD bit allows the user to simulate a single bit fault during Flash array read operations and check the associated interrupt routine. The FSFD bit is cleared by writing a 0 to FSFD. The FECCR registers will not be updated during the Flash array read operation with FSFD set unless an actual single bit fault is detected.  
  0 Flash array read operations will set the SFDIF flag in the FERSTAT register only if a single bit fault is detected  
  1 Flash array read operation will force the SFDIF flag in the FERSTAT register to be set (see Section 13.3.2.7) and an interrupt will be generated as long as the SFDIE interrupt enable in the FERCNFG register is set (see Section 13.3.2.6) |

### 13.3.2.6 Flash Error Configuration Register (FERCNFG)

The FERCNFG register enables the Flash error interrupts for the FERSTAT flags.

![Figure 13-10. Flash Error Configuration Register (FERCNFG)](offset: module base + 0x0005)

All assigned bits in the FERCNFG register are readable and writable.
13.3.2.7 Flash Status Register (FSTAT)

The FSTAT register reports the operational status of the Flash module.

Table 13-13. FERCNFG Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1 DFDIE | **Double Bit Fault Detect Interrupt Enable** — The DFDIE bit controls interrupt generation when a double bit fault is detected during a Flash block read operation.  
0 DFDIF interrupt disabled  
1 An interrupt will be requested whenever the DFDIF flag is set (see Section 13.3.2.8) |
| 0 SFDIE | **Single Bit Fault Detect Interrupt Enable** — The SFDIE bit controls interrupt generation when a single bit fault is detected during a Flash block read operation.  
0 SFDIF interrupt disabled whenever the SFDIF flag is set (see Section 13.3.2.8)  
1 An interrupt will be requested whenever the SFDIF flag is set (see Section 13.3.2.8) |

Table 13-14. FSTAT Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7 CCIF | **Command Complete Interrupt Flag** — The CCIF flag indicates that a Flash command has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a command and CCIF will stay low until command completion or command violation.  
0 Flash command in progress  
1 Flash command has completed |
| 5 ACCERR | **Flash Access Error Flag** — The ACCERR bit indicates an illegal access has occurred to the Flash memory caused by either a violation of the command write sequence (see Section 13.4.3.2) or issuing an illegal Flash command. While ACCERR is set, the CCIF flag cannot be cleared to launch a command. The ACCERR bit is cleared by writing a 1 to ACCERR. Writing a 0 to the ACCERR bit has no effect on ACCERR.  
0 No access error detected  
1 Access error detected |
| 4 FPVIOL | **Flash Protection Violation Flag** — The FPVIOL bit indicates an attempt was made to program or erase an address in a protected area of P-Flash or D-Flash memory during a command write sequence. The FPVIOL bit is cleared by writing a 1 to FPVIOL. Writing a 0 to the FPVIOL bit has no effect on FPVIOL. While FPVIOL is set, it is not possible to launch a command or start a command write sequence.  
0 No protection violation detected  
1 Protection violation detected |
### 13.3.2.8 Flash Error Status Register (FERSTAT)

The FERSTAT register reflects the error status of internal Flash operations.

![Figure 13-12. Flash Error Status Register (FERSTAT)](image)

All flags in the FERSTAT register are readable and only writable to clear the flag.

#### Table 13-14. FSTAT Field Descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 3 MGBUSY | Memory Controller Busy Flag — The MGBUSY flag reflects the active state of the Memory Controller.  
0 Memory Controller is idle  
1 Memory Controller is busy executing a Flash command (CCIF = 0) |
| 2 RSVD | Reserved Bit — This bit is reserved and always reads 0. |
| 1–0 MGSTAT[1:0] | Memory Controller Command Completion Status Flag — One or more MGSTAT flag bits are set if an error is detected during execution of a Flash command or during the Flash reset sequence. See Section 13.4.5, “Flash Command Description,” and Section 13.6, “Initialization” for details. |

#### Table 13-15. FERSTAT Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1 DFDIF | Double Bit Fault Detect Interrupt Flag — The setting of the DFDIF flag indicates that a double bit fault was detected in the stored parity and data bits during a Flash array read operation or that a Flash array read operation was attempted on a Flash block that was under a Flash command operation.1) The DFDIF flag is cleared by writing a 1 to DFDIF. Writing a 0 to DFDIF has no effect on DFDIF.  
0 No double bit fault detected  
1 Double bit fault detected or an invalid Flash array read operation attempted |
| 0 SFDIF | Single Bit Fault Detect Interrupt Flag — With the IGNSF bit in the FCNFG register clear, the SFDIF flag indicates that a single bit fault was detected in the stored parity and data bits during a Flash array read operation or that a Flash array read operation was attempted on a Flash block that was under a Flash command operation.1) The SFDIF flag is cleared by writing a 1 to SFDIF. Writing a 0 to SFDIF has no effect on SFDIF.  
0 No single bit fault detected  
1 Single bit fault detected and corrected or an invalid Flash array read operation attempted |

1. The single bit fault and double bit fault flags are mutually exclusive for parity errors (an ECC fault occurrence can be either single fault or double fault but never both). A simultaneous access collision (read attempted while command running) is indicated when both SFDIF and DFDIF flags are high.

### 13.3.2.9 P-Flash Protection Register (FPROT)

The FPROT register defines which P-Flash sectors are protected against program and erase operations.
The (unreserved) bits of the FPROT register are writable with the restriction that the size of the protected region can only be increased (see Section 13.3.2.9.1, “P-Flash Protection Restrictions,” and Table 13-20).

During the reset sequence, the FPROT register is loaded with the contents of the P-Flash protection byte in the Flash configuration field at global address 0x3_FFOC located in P-Flash memory (see Table 13-3) as indicated by reset condition ‘F’ in Figure 13-13. To change the P-Flash protection that will be loaded during the reset sequence, the upper sector of the P-Flash memory must be unprotected, then the P-Flash protection byte must be reprogrammed. If a double bit fault is detected while reading the P-Flash phrase containing the P-Flash protection byte during the reset sequence, the FPOPEN bit will be cleared and remaining bits in the FPROT register will be set to leave the P-Flash memory fully protected.

Trying to alter data in any protected area in the P-Flash memory will result in a protection violation error and the FPVIOL bit will be set in the FSTAT register. The block erase of a P-Flash block is not possible if any of the P-Flash sectors contained in the same P-Flash block are protected.

Table 13-16. FPROT Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td><strong>Flash Protection Operation Enable</strong> — The FOPEN bit determines the protection function for program or erase operations as shown in Table 13-17 for the P-Flash block.</td>

<tr>
<td>1–0</td>
<td><strong>Flash Protection Lower Address Size</strong> — The FPLS bits determine the size of the protected/unprotected area in P-Flash memory as shown in Table 13-19. The FPLS bits can only be written to while the FPLDIS bit is set.</td>
</tr>
</tbody>
</table>

= Unimplemented or Reserved
All possible P-Flash protection scenarios are shown in Figure 13-14. Although the protection scheme is loaded from the Flash memory at global address 0x3_FF0C during the reset sequence, it can be changed by the user. The P-Flash protection scheme can be used by applications requiring reprogramming in single chip mode while providing as much protection as possible if reprogramming is not required.
Figure 13-14. P-Flash Protection Scenarios
13.3.2.9.1 P-Flash Protection Restrictions

The general guideline is that P-Flash protection can only be added and not removed. Table 13-20 specifies all valid transitions between P-Flash protection scenarios. Any attempt to write an invalid scenario to the FPROT register will be ignored. The contents of the FPROT register reflect the active protection scenario. See the FPHS and FPLS bit descriptions for additional restrictions.

</tbody>
</table>

1. Allowed transitions marked with X, see Figure 13-14 for a definition of the scenarios.

13.3.2.10 D-Flash Protection Register (DFPROT)

The DFPROT register defines which D-Flash sectors are protected against program and erase operations.

During the reset sequence, the DFPROT register is loaded with the contents of the D-Flash protection byte in the Flash configuration field at global address 0x3_FF0D located in P-Flash memory (see Table 13-3) as indicated by reset condition F in Figure 13-15. To change the D-Flash protection that will be loaded during the reset sequence, the P-Flash sector containing the D-Flash protection byte must be unprotected, then the D-Flash protection byte must be programmed. If a double bit fault is detected while reading the...
P-Flash phrase containing the D-Flash protection byte during the reset sequence, the DOPEN bit will be cleared and DPS bits will be set to leave the D-Flash memory fully protected.

Trying to alter data in any protected area in the D-Flash memory will result in a protection violation error and the FPVIOL bit will be set in the FSTAT register. Block erase of the D-Flash memory is not possible if any of the D-Flash sectors are protected.

### 13.3.2.11 Flash Common Command Object Register (FCCOB)

The FCCOB is an array of six words addressed via the CCOBIX index found in the FCCOBIX register. Byte wide reads and writes are allowed to the FCCOB register.

</table>

**Table 13-22. D-Flash Protection Address Range**

13.3.2.11 Flash Common Command Object Register (FCCOB)

The FCCOB is an array of six words addressed via the CCOBIX index found in the FCCOBIX register. Byte wide reads and writes are allowed to the FCCOB register.
13.3.2.11.1 FCCOB - NVM Command Mode

NVM command mode uses the indexed FCCOB register to provide a command code and its relevant parameters to the Memory Controller. The user first sets up all required FCCOB fields and then initiates the command’s execution by writing a 1 to the CCIF bit in the FSTAT register (a 1 written by the user clears the CCIF command completion flag to 0). When the user clears the CCIF bit in the FSTAT register all FCCOB parameter fields are locked and cannot be changed by the user until the command completes (as evidenced by the Memory Controller returning CCIF to 1). Some commands return information to the FCCOB register array.

The generic format for the FCCOB parameter fields in NVM command mode is shown in Table 13-23. The return values are available for reading after the CCIF flag in the FSTAT register has been returned to 1 by the Memory Controller. Writes to the unimplemented parameter fields (CCOBIX = 110 and CCOBIX = 111) are ignored with reads from these fields returning 0x0000.

Table 13-23 shows the generic Flash command format. The high byte of the first word in the CCOB array contains the command code, followed by the parameters for this specific Flash command. For details on the FCCOB settings required by each command, see the Flash command descriptions in Section 13.4.5.

All bits in the FRSV1 register read 0 and are not writable.

13.3.2.13 Flash Reserved2 Register (FRSV2)

This Flash register is reserved for factory testing.

All bits in the FRSV2 register read 0 and are not writable.

13.3.2.14 Flash Reserved3 Register (FRSV3)

This Flash register is reserved for factory testing.
All bits in the FRSV3 register read 0 and are not writable.

### 13.3.2.15 Flash Reserved4 Register (FRSV4)

This Flash register is reserved for factory testing.

![Figure 13-20. Flash Reserved3 Register (FRSV3)](image)

All bits in the FRSV4 register read 0 and are not writable.

### 13.3.2.16 Flash Option Register (FOPT)

The FOPT register is the Flash option register.

![Figure 13-21. Flash Reserved4 Register (FRSV4)](image)

All bits in the FOPT register are readable but are not writable.

During the reset sequence, the FOPT register is loaded from the Flash nonvolatile byte in the Flash configuration field at global address 0x3_FF0E located in P-Flash memory (see Table 13-3) as indicated by reset condition F in Figure 13-22. If a double bit fault is detected while reading the P-Flash phrase containing the Flash nonvolatile byte during the reset sequence, all bits in the FOPT register will be set.

S12P-Family Reference Manual, Rev. 1.13

This Flash register is reserved for factory testing.
13.4 Functional Description

13.4.1 Modes of Operation

The FTMRC128K1 module provides the modes of operation shown in Table 13-25. The operating mode is determined by module-level inputs and affects the FCLKDIV, FCNFG, and DFPROT registers, Scratch RAM writes, and the command set availability (see Table 13-27).

<table>
<thead>
<tr>
<th>Operating Mode</th>
<th>FTMRC Input</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal:</td>
<td>0</td>
</tr>
<tr>
<td>Special:</td>
<td>1</td>
</tr>
</tbody>
</table>

13.4.2 IFR Version ID Word

The version ID word is stored in the IFR at address 0x0_40B6. The contents of the word are defined in Table 13-26.

<table>
<thead>
<tr>
<th>[15:4]</th>
<th>[3:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>VERNUM</td>
</tr>
</tbody>
</table>

- VERNUM: Version number. The first version is number 0b_0001 with both 0b_0000 and 0b_1111 meaning ‘none’.

13.4.3 Flash Command Operations

Flash command operations are used to modify Flash memory contents.

The next sections describe:
• How to write the FCLKDIV register that is used to generate a time base (FCLK) derived from BUSCLK for Flash program and erase command operations
• The command write sequence used to set Flash command parameters and launch execution
• Valid Flash commands available for execution

13.4.3.1 Writing the FCLKDIV Register

Prior to issuing any Flash program or erase command after a reset, the user is required to write the FCLKDIV register to divide BUSCLK down to a target FCLK of 1 MHz. Table 13-7 shows recommended values for the FDIV field based on BUSCLK frequency.

**NOTE**

Programming or erasing the Flash memory cannot be performed if the bus clock runs at less than 0.8 MHz. Setting FDIV too high can destroy the Flash memory due to overstress. Setting FDIV too low can result in incomplete programming or erasure of the Flash memory cells.

When the FCLKDIV register is written, the FDIVLD bit is set automatically. If the FDIVLD bit is 0, the FCLKDIV register has not been written since the last reset. If the FCLKDIV register has not been written, any Flash program or erase command loaded during a command write sequence will not execute and the ACCERR bit in the FSTAT register will set.

13.4.3.2 Command Write Sequence

The Memory Controller will launch all valid Flash commands entered using a command write sequence.

Before launching a command, the ACCERR and FPVIOL bits in the FSTAT register must be clear (see Section 13.3.2.7) and the CCIF flag should be tested to determine the status of the current command write sequence. If CCIF is 0, the previous command write sequence is still active, a new command write sequence cannot be started, and all writes to the FCCOB register are ignored.

**CAUTION**

Writes to any Flash register must be avoided while a Flash command is active (CCIF=0) to prevent corruption of Flash register contents and Memory Controller behavior.

13.4.3.2.1 Define FCCOB Contents

The FCCOB parameter fields must be loaded with all required parameters for the Flash command being executed. Access to the FCCOB parameter fields is controlled via the CCOBIX bits in the FCCOBIX register (see Section 13.3.2.3).

The contents of the FCCOB parameter fields are transferred to the Memory Controller when the user clears the CCIF command completion flag in the FSTAT register (writing 1 clears the CCIF to 0). The CCIF flag will remain clear until the Flash command has completed. Upon completion, the Memory Controller will return CCIF to 1 and the FCCOB register will be used to communicate any results. The flow for a generic command write sequence is shown in Figure 13-26.

</tr>
</tbody>
</table>
13.4.4 Allowed Simultaneous P-Flash and D-Flash Operations

Only the operations marked ‘OK’ in Table 13-30 are permitted to be run simultaneously on the Program Flash and Data Flash blocks. Some operations cannot be executed simultaneously because certain hardware resources are shared by the two memories. The priority has been placed on permitting Program Flash reads while program and erase operations execute on the Data Flash, providing read (P-Flash) while write (D-Flash) functionality.

Table 13-30. Allowed P-Flash and D-Flash Simultaneous Operations

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1. A ‘Margin Read’ is any read after executing the margin setting commands ‘Set User Margin Level’ or ‘Set Field Margin Level’ with anything but the ‘normal’ level specified.
2. See the Note on margin settings in Section 13.4.5.12 and Section 13.4.5.13.
3. The ‘Mass Erase’ operations are commands ‘Erase All Blocks’ and ‘Erase Flash Block’

13.4.5 Flash Command Description

This section provides details of all available Flash commands launched by a command write sequence. The ACCERR bit in the FSTAT register will be set during the command write sequence if any of the following illegal steps are performed, causing the command not to be processed by the Memory Controller:

- Starting any command write sequence that programs or erases Flash memory before initializing the FCLKDIV register
- Writing an invalid command as part of the command write sequence
- For additional possible errors, refer to the error handling table provided for each command
If a Flash block is read during execution of an algorithm (CCIF = 0) on that same block, the read operation will return invalid data. If the SFDIF or DFDIF flags were not previously set when the invalid read operation occurred, both the SFDIF and DFDIF flags will be set.

If the ACCERR or FPVIOL bits are set in the FSTAT register, the user must clear these bits before starting any command write sequence (see Section 13.3.2.7).

CAUTION
A Flash word or phrase must be in the erased state before being programmed. Cumulative programming of bits within a Flash word or phrase is not allowed.

### 13.4.5.1 Erase Verify All Blocks Command

The Erase Verify All Blocks command will verify that all P-Flash and D-Flash blocks have been erased.

<table>
<thead>
<tr>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x01</td>
</tr>
</tbody>
</table>

Upon clearing CCIF to launch the Erase Verify All Blocks command, the Memory Controller will verify that the entire Flash memory space is erased. The CCIF flag will set after the Erase Verify All Blocks operation has completed.

<table>
<thead>
<tr>
<th>Register</th>
<th>Error Bit</th>

<td>MGSTAT0</td>
<td>Set if any non-correctable errors have been encountered during the read</td>
</tr>
</tbody>
</table>

### 13.4.5.2 Erase Verify Block Command

The Erase Verify Block command allows the user to verify that an entire P-Flash or D-Flash block has been erased. The FCCOB upper global address bits determine which block must be verified.

<table>
<thead>
<tr>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x02</td>
</tr>
</tbody>
</table>

Upon clearing CCIF to launch the Erase Verify Block command, the Memory Controller will verify that the selected P-Flash or D-Flash block is erased. The CCIF flag will set after the Erase Verify Block operation has completed.
### 13.4.5.3 Erase Verify P-Flash Section Command

The Erase Verify P-Flash Section command will verify that a section of code in the P-Flash memory is erased. The Erase Verify P-Flash Section command defines the starting point of the code to be verified and the number of phrases.

<table>
<thead>
<tr>
<th>Register</th>

### 13.4.5.4 Read Once Command

The Read Once command provides read access to a reserved 64 byte field (8 phrases) located in the nonvolatile information register of P-Flash. The Read Once field is programmed using the Program Once
command described in Section 13.4.5.6. The Read Once command must not be executed from the Flash block containing the Program Once reserved field to avoid code runaway.

**Table 13-37. Read Once Command FCCOB Requirements**

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0x04</td>
</tr>
<tr>
<td>001</td>
<td>Read Once phrase index (0x0000 - 0x0007)</td>
</tr>
<tr>
<td>010</td>
<td>Read Once word 0 value</td>
</tr>
<tr>
<td>011</td>
<td>Read Once word 1 value</td>
</tr>
<tr>
<td>100</td>
<td>Read Once word 2 value</td>
</tr>
<tr>
<td>101</td>
<td>Read Once word 3 value</td>
</tr>
</tbody>
</table>

Upon clearing CCIF to launch the Read Once command, a Read Once phrase is fetched and stored in the FCCOB indexed register. The CCIF flag will set after the Read Once operation has completed. Valid phrase index values for the Read Once command range from 0x0000 to 0x0007. During execution of the Read Once command, any attempt to read addresses within P-Flash block will return invalid data.

**Table 13-38. Read Once Command Error Handling**

</tr>
<tr>
<td></td>
<td>MGSTAT0</td>
<td>Set if any non-correctable errors have been encountered during the read</td>
</tr>
</tbody>
</table>

### 13.4.5.5 Program P-Flash Command

The Program P-Flash operation will program a previously erased phrase in the P-Flash memory using an embedded algorithm.

**CAUTION**

A P-Flash phrase must be in the erased state before being programmed. Cumulative programming of bits within a Flash phrase is not allowed.

**Table 13-39. Program P-Flash Command FCCOB Requirements**

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>

<tr>
<td>010</td>
<td>Word 0 program value</td>
</tr>
</tbody>
</table>

S12P-Family Reference Manual, Rev. 1.13
Upon clearing CCIF to launch the Program P-Flash command, the Memory Controller will program the data words to the supplied global address and will then proceed to verify the data words read back as expected. The CCIF flag will set after the Program P-Flash operation has completed.

### Table 13-39. Program P-Flash Command FCCOB Requirements

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>011</td>

</tr>
<tr>
<td>100</td>
<td>Word 2 program value</td>
</tr>
<tr>
<td>101</td>
<td>Word 3 program value</td>
</tr>
</tbody>
</table>

1. Global address [2:0] must be 000

### 13.4.5.6 Program Once Command

The Program Once command restricts programming to a reserved 64 byte field (8 phrases) in the nonvolatile information register located in P-Flash. The Program Once reserved field can be read using the Read Once command as described in Section 13.4.5.4. The Program Once command must only be issued once since the nonvolatile information register in P-Flash cannot be erased. The Program Once command must not be executed from the Flash block containing the Program Once reserved field to avoid code runaway.

### Table 13-40. Program P-Flash Command Error Handling

<table>
<thead>
<tr>
<th>Register</th>
<th>Error Bit</th>
<th>Error Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>FSTAT</td>
<td>ACCERR</td>
<td>Set if CCOBIX[2:0] != 101 at command launch</td>
</tr>
<tr>

<td>Program Once word 1 value</td>
</tr>
<tr>
<td>100</td>
<td>Program Once word 2 value</td>
</tr>
<tr>
<td>101</td>
<td>Program Once word 3 value</td>
</tr>
</tbody>
</table>
Upon clearing CCIF to launch the Program Once command, the Memory Controller first verifies that the selected phrase is erased. If erased, then the selected phrase will be programmed and then verified with read back. The CCIF flag will remain clear, setting only after the Program Once operation has completed.

The reserved nonvolatile information register accessed by the Program Once command cannot be erased and any attempt to program one of these phrases a second time will not be allowed. Valid phrase index values for the Program Once command range from 0x0000 to 0x0007. During execution of the Program Once command, any attempt to read addresses within P-Flash will return invalid data.

### 13.4.5.7 Erase All Blocks Command

The Erase All Blocks operation will erase the entire P-Flash and D-Flash memory space.

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
<th>FSTAT Error Bit</th>
<th>Error Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0x08</td>
<td>ACCERR</td>
<td>Set if CCOBIX[2:0] != 101 at command launch</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Set if command not available in current mode (see Table 13-27)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Set if an invalid phrase index is supplied</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Set if the requested phrase has already been programmed(1)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>FPVIOL</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MGSTAT1</td>
<td>Set if any errors have been encountered during the verify operation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MGSTAT0</td>
<td>Set if any non-correctable errors have been encountered during the verify operation</td>
</tr>
</tbody>
</table>

1. If a Program Once phrase is initially programmed to 0xFFFF_FFFF_FFFF_FFFF, the Program Once command will be allowed to execute again on that same phrase.

### Table 13-43. Erase All Blocks Command FCCOB Requirements

Upon clearing CCIF to launch the Erase All Blocks command, the Memory Controller will erase the entire Flash memory space and verify that it is erased. If the Memory Controller verifies that the entire Flash memory space was properly erased, security will be released. During the execution of this command (CCIF=0) the user must not write to any Flash module register. The CCIF flag will set after the Erase All Blocks operation has completed.
13.4.5.8 Erase Flash Block Command

The Erase Flash Block operation will erase all addresses in a P-Flash or D-Flash block.

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0x09</td>
</tr>
<tr>
<td>001</td>
<td></td>
</tr>
</tbody>
</table>

Upon clearing CCIF to launch the Erase Flash Block command, the Memory Controller will erase the selected Flash block and verify that it is erased. The CCIF flag will set after the Erase Flash Block operation has completed.

<table>
<thead>
<tr>
<th>Register</th>
<th>Error Bit</th>
<th>Error Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>FSTAT</td>
<td>ACCERR</td>
<td>Set if CCOBIX[2:0] ! = 000 at command launch</td>

</tr>
<tr>
<td></td>
<td>MGSTAT0</td>
<td>Set if any non-correctable errors have been encountered during the verify operation</td>
</tr>
</tbody>
</table>

13.4.5.9 Erase P-Flash Sector Command

The Erase P-Flash Sector operation will erase all addresses in a P-Flash sector.
Upon clearing CCIF to launch the Erase P-Flash Sector command, the Memory Controller will erase the selected Flash sector and then verify that it is erased. The CCIF flag will be set after the Erase P-Flash Sector operation has completed.

### Table 13-47. Erase P-Flash Sector Command FCCOB Requirements

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>

<td>MGSTAT1</td>
<td>Set if any errors have been encountered during the verify operation</td>
</tr>
<tr>
<td></td>
<td>MGSTAT0</td>
<td>Set if any non-correctable errors have been encountered during the verify operation</td>
</tr>
</tbody>
</table>

### 13.4.5.10 Unsecure Flash Command

The Unsecure Flash command will erase the entire P-Flash and D-Flash memory space and, if the erase is successful, will release security.

### Table 13-49. Unsecure Flash Command FCCOB Requirements

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
<th>Error Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0x0B</td>
<td>Not required</td>
</tr>
</tbody>
</table>

Upon clearing CCIF to launch the Unsecure Flash command, the Memory Controller will erase the entire P-Flash and D-Flash memory space and verify that it is erased. If the Memory Controller verifies that the entire Flash memory space was properly erased, security will be released. If the erase verify is not successful, the Unsecure Flash operation sets MGSTAT1 and terminates without changing the security state. During the execution of this command (CCIF=0) the user must not write to any Flash module register. The CCIF flag is set after the Unsecure Flash operation has completed.
13.4.5.11 Verify Backdoor Access Key Command

The Verify Backdoor Access Key command will only execute if it is enabled by the KEYEN bits in the FSEC register (see Table 13-9). The Verify Backdoor Access Key command releases security if user-supplied keys match those stored in the Flash security bytes of the Flash configuration field (see Table 13-3). The Verify Backdoor Access Key command must not be executed from the Flash block containing the backdoor comparison key to avoid code runaway.

Table 13-50. Unsecure Flash Command Error Handling

<table>
<thead>
<tr>
<th>Register</th>
<th>Error Bit</th>
<th>Error Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>FSTAT</td>
<td>ACCERR</td>
<td>Set if CCOBIX[2:0] != 000 at command launch</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set if command not available in current mode (see Table 13-27)</td>
</tr>
<tr>
<td></td>
<td>FPVIOL</td>
<td>Set if any area of the P-Flash or D-Flash memory is protected</td>
</tr>
<tr>
<td></td>
<td>MGSTAT1</td>
<td>Set if any errors have been encountered during the verify operation</td>
</tr>
<tr>
<td></td>
<td>MGSTAT0</td>
<td>Set if any non-correctable errors have been encountered during the verify operation</td>
</tr>
</tbody>
</table>

Table 13-51. Verify Backdoor Access Key Command FCCOB Requirements

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0x0C Not required</td>
</tr>
<tr>
<td>001</td>
<td>Key 0</td>
</tr>
<tr>
<td>010</td>
<td>Key 1</td>
</tr>
<tr>
<td>011</td>
<td>Key 2</td>
</tr>
<tr>
<td>100</td>
<td>Key 3</td>
</tr>
</tbody>
</table>

Upon clearing CCIF to launch the Verify Backdoor Access Key command, the Memory Controller will check the FSEC KEYEN bits to verify that this command is enabled. If not enabled, the Memory Controller sets the ACCERR bit in the FSTAT register and terminates. If the command is enabled, the Memory Controller compares the key provided in FCCOB to the backdoor comparison key in the Flash configuration field with Key 0 compared to 0x3_FF00, etc. If the backdoor keys match, security will be released. If the backdoor keys do not match, security is not released and all future attempts to execute the Verify Backdoor Access Key command are aborted (set ACCERR) until a reset occurs. The CCIF flag is set after the Verify Backdoor Access Key operation has completed.
13.4.5.12 Set User Margin Level Command

The Set User Margin Level command causes the Memory Controller to set the margin level for future read operations of the P-Flash or D-Flash block.

Table 13-53. Set User Margin Level Command FCCOB Requirements

<table>
<thead>
<tr>
<th>FCCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0x00</td>
</tr>
<tr>
<td></td>
<td>Global address [17:16] to identify the Flash block</td>
</tr>
<tr>
<td>001</td>
<td>Margin level setting</td>
</tr>
</tbody>
</table>

Upon clearing CCIF to launch the Set User Margin Level command, the Memory Controller will set the user margin level for the targeted block and then set the CCIF flag.

**NOTE**

When the D-Flash block is targeted, the D-Flash user margin levels are applied only to the D-Flash reads. However, when the P-Flash block is targeted, the P-Flash user margin levels are applied to both P-Flash and D-Flash reads. It is not possible to apply user margin levels to the P-Flash block only.

Valid margin level settings for the Set User Margin Level command are defined in Table 13-54.

Table 13-54. Valid Set User Margin Level Settings

<table>
<thead>
<tr>
<th>CCOB (CCOBIX=001)</th>
<th>Level Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0000</td>
<td>Return to Normal Level</td>
</tr>
<tr>
<td>0x0001</td>
<td>User Margin-1 Level(1)</td>
</tr>
<tr>
<td>0x0002</td>
<td>User Margin-0 Level(2)</td>
</tr>
</tbody>
</table>

1. Read margin to the erased state
2. Read margin to the programmed state
NOTE
User margin levels can be used to check that Flash memory contents have adequate margin for normal level read operations. If unexpected results are encountered when checking Flash memory contents at user margin levels, a potential loss of information has been detected.

### 13.4.5.13 Set Field Margin Level Command

The Set Field Margin Level command, valid in special modes only, causes the Memory Controller to set the margin level specified for future read operations of the P-Flash or D-Flash block.

#### Table 13-56. Set Field Margin Level Command FCCOB Requirements

<table>
<thead>
<tr>
<th>FCCOB Parameters</th>
<th>CCOBIX[2:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0E</td>
<td>000</td>
</tr>
<tr>
<td>Margin level setting</td>
<td>001</td>
</tr>
</tbody>
</table>

Upon clearing CCIF to launch the Set Field Margin Level command, the Memory Controller will set the field margin level for the targeted block and then set the CCIF flag.

**NOTE**

When the D-Flash block is targeted, the D-Flash field margin levels are applied only to the D-Flash reads. However, when the P-Flash block is targeted, the P-Flash field margin levels are applied to both P-Flash and D-Flash reads. It is not possible to apply field margin levels to the P-Flash block only.

Valid margin level settings for the Set Field Margin Level command are defined in Table 13-57.
Table 13-57. Valid Set Field Margin Level Settings

<table>
<thead>
<tr>
<th>CCOB (CCOBIX=001)</th>
<th>Level Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0000</td>

</tr>
<tr>
<td></td>
<td>MGSTAT1</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>MGSTAT0</td>
<td>None</td>
</tr>
</tbody>
</table>

CAUTION

Field margin levels must only be used during verify of the initial factory programming.

NOTE

Field margin levels can be used to check that Flash memory contents have adequate margin for data retention at the normal level setting. If unexpected results are encountered when checking Flash memory contents at field margin levels, the Flash memory contents should be erased and reprogrammed.

13.4.5.14 Erase Verify D-Flash Section Command

The Erase Verify D-Flash Section command will verify that a section of code in the D-Flash is erased. The Erase Verify D-Flash Section command defines the starting point of the data to be verified and the number of words.
Upon clearing CCIF to launch the Erase Verify D-Flash Section command, the Memory Controller will verify the selected section of D-Flash memory is erased. The CCIF flag will set after the Erase Verify D-Flash Section operation has completed.

### Table 13-59. Erase Verify D-Flash Section Command FCCOB Requirements

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0x10 Global address [17:16] to identify the D-Flash block</td>
</tr>
<tr>
<td>001</td>
<td>Global address [15:0] of the first word to be verified</td>
</tr>
<tr>
<td>010</td>
<td>Number of words to be verified</td>
</tr>
</tbody>
</table>

### Table 13-60. Erase Verify D-Flash Section Command Error Handling

<table>
<thead>
<tr>
<th>Register</th>
<th>Error Bit</th>

</tr>
<tr>
<td></td>
<td></td>
<td>Set if an invalid global address [17:0] is supplied</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set if a misaligned word address is supplied (global address [0] != 0)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set if the requested section breaches the end of the D-Flash block</td>
</tr>
<tr>
<td></td>
<td>FPVIOL</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>MGSTAT1</td>
<td>Set if any errors have been encountered during the read</td>
</tr>
<tr>
<td></td>
<td>MGSTAT0</td>
<td>Set if any non-correctable errors have been encountered during the read</td>
</tr>
</tbody>
</table>

### 13.4.5.15 Program D-Flash Command

The Program D-Flash operation programs one to four previously erased words in the D-Flash block. The Program D-Flash operation will confirm that the targeted location(s) were successfully programmed upon completion.

**CAUTION**

A Flash word must be in the erased state before being programmed. Cumulative programming of bits within a Flash word is not allowed.

### Table 13-61. Program D-Flash Command FCCOB Requirements

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0x11 Global address [17:16] to identify the D-Flash block</td>
</tr>
<tr>
<td>001</td>
<td>Global address [15:0] of word to be programmed</td>
</tr>
<tr>
<td>010</td>
<td>Word 0 program value</td>
</tr>
<tr>
<td>011</td>
<td>Word 1 program value, if desired</td>
</tr>
<tr>
<td>100</td>
<td>Word 2 program value, if desired</td>
</tr>
</tbody>
</table>
Upon clearing CCIF to launch the Program D-Flash command, the user-supplied words will be transferred to the Memory Controller and be programmed if the area is unprotected. The CCOBIX index value at Program D-Flash command launch determines how many words will be programmed in the D-Flash block. The CCIF flag is set when the operation has completed.

### Table 13-61. Program D-Flash Command FCCOB Requirements

</tbody>
</table>

### 13.4.5.16 Erase D-Flash Sector Command

The Erase D-Flash Sector operation will erase all addresses in a sector of the D-Flash block.

### Table 13-63. Erase D-Flash Sector Command FCCOB Requirements

<table>
<thead>
<tr>
<th>CCOBIX[2:0]</th>
<th>FCCOB Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0x12 Global address [17:16] to identify D-Flash block</td>
</tr>
<tr>
<td>001</td>
<td>Global address [15:0] anywhere within the sector to be erased. See Section 13.1.2.2 for D-Flash sector size.</td>
</tr>
</tbody>
</table>

Upon clearing CCIF to launch the Erase D-Flash Sector command, the Memory Controller will erase the selected Flash sector and verify that it is erased. The CCIF flag will set after the Erase D-Flash Sector operation has completed.
13.4.6 Interrupts

The Flash module can generate an interrupt when a Flash command operation has completed or when a Flash command operation has detected an ECC fault.

### Table 13-65. Flash Interrupt Sources

<table>
<thead>
<tr>
<th>Interrupt Source</th>
<th>Interrupt Flag</th>
<th>Local Enable</th>
<th>Global (CCR) Mask</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flash Command Complete</td>
<td>CCIF (FSTAT register)</td>
<td>CCIE (FCNFG register)</td>
<td>I Bit</td>
</tr>
<tr>
<td>ECC Double Bit Fault on Flash Read</td>
<td>DFDIF (FERSTAT register)</td>
<td>DFDIE (FERCNFG register)</td>
<td>I Bit</td>
</tr>
<tr>
<td>ECC Single Bit Fault on Flash Read</td>
<td>SFDIF (FERSTAT register)</td>
<td>SFDIE (FERCNFG register)</td>
<td>I Bit</td>
</tr>
</tbody>
</table>

**NOTE**

Vector addresses and their relative interrupt priority are determined at the MCU level.

13.4.6.1 Description of Flash Interrupt Operation

The Flash module uses the CCIF flag in combination with the CCIE interrupt enable bit to generate the Flash command interrupt request. The Flash module uses the DFDIF and SFDIF flags in combination with the DFDIE and SFDIE interrupt enable bits to generate the Flash error interrupt request. For a detailed description of the register bits involved, refer to Section 13.3.2.5, “Flash Configuration Register (FCNFG)”, Section 13.3.2.6, “Flash Error Configuration Register (FERCNFG)”, Section 13.3.2.7, “Flash Status Register (FSTAT)”, and Section 13.3.2.8, “Flash Error Status Register (FERSTAT)”.

The logic used for generating the Flash module interrupts is shown in Figure 13-27.
13.4.7 Wait Mode

The Flash module is not affected if the MCU enters wait mode. The Flash module can recover the MCU from wait via the CCIF interrupt (see Section 13.4.6, “Interrupts”).

13.4.8 Stop Mode

If a Flash command is active (CCIF = 0) when the MCU requests stop mode, the current Flash operation will be completed before the CPU is allowed to enter stop mode.

13.5 Security

The Flash module provides security information to the MCU. The Flash security state is defined by the SEC bits of the FSEC register (see Table 13-10). During reset, the Flash module initializes the FSEC register using data read from the security byte of the Flash configuration field at global address 0x3_FF0F. The security state out of reset can be permanently changed by programming the security byte assuming that the MCU is starting from a mode where the necessary P-Flash erase and program commands are available and that the upper region of the P-Flash is unprotected. If the Flash security byte is successfully programmed, its new value will take affect after the next MCU reset.

The following subsections describe these security-related subjects:

- Unsecuring the MCU using Backdoor Key Access
- Unsecuring the MCU in Special Single Chip Mode using BDM
- Mode and Security Effects on Flash Command Availability

13.5.1 Unsecuring the MCU using Backdoor Key Access

The MCU may be unsecured by using the backdoor key access feature which requires knowledge of the contents of the backdoor keys (four 16-bit words programmed at addresses 0x3_FF00-0x3_FF07). If the KEYEN[1:0] bits are in the enabled state (see Section 13.3.2.2), the Verify Backdoor Access Key command (see Section 13.4.5.11) allows the user to present four prospective keys for comparison to the keys stored in the Flash memory via the Memory Controller. If the keys presented in the Verify Backdoor Access Key command match the backdoor keys stored in the Flash memory, the SEC bits in the FSEC
register (see Table 13-10) will be changed to unsecure the MCU. Key values of 0x0000 and 0xFFFF are not permitted as backdoor keys. While the Verify Backdoor Access Key command is active, P-Flash memory and D-Flash memory will not be available for read access and will return invalid data.

The user code stored in the P-Flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN[1:0] bits are in the enabled state (see Section 13.3.2.2), the MCU can be unsecured by the backdoor key access sequence described below:

1. Follow the command sequence for the Verify Backdoor Access Key command as explained in Section 13.4.5.11
2. If the Verify Backdoor Access Key command is successful, the MCU is unsecured and the SEC[1:0] bits in the FSEC register are forced to the unsecure state of 10

The Verify Backdoor Access Key command is monitored by the Memory Controller and an illegal key will prohibit future use of the Verify Backdoor Access Key command. A reset of the MCU is the only method to re-enable the Verify Backdoor Access Key command. The security as defined in the Flash security byte (0x3_FF0F) is not changed by using the Verify Backdoor Access Key command sequence. The backdoor keys stored in addresses 0x3_FF00-0x3_FF07 are unaffected by the Verify Backdoor Access Key command sequence. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the Flash protection register, FPROT.

After the backdoor keys have been correctly matched, the MCU will be unsecured. After the MCU is unsecured, the sector containing the Flash security byte can be erased and the Flash security byte can be reprogrammed to the unsecure state, if desired. In the unsecure state, the user has full control of the contents of the backdoor keys by programming addresses 0x3_FF00-0x3_FF07 in the Flash configuration field.

**13.5.2 Unsecuring the MCU in Special Single Chip Mode using BDM**

A secured MCU can be unsecured in special single chip mode by using the following method to erase the P-Flash and D-Flash memory:

1. Reset the MCU into special single chip mode
2. Delay while the BDM executes the Erase Verify All Blocks command write sequence to check if the P-Flash and D-Flash memories are erased
3. Send BDM commands to disable protection in the P-Flash and D-Flash memory
4. Execute the Erase All Blocks command write sequence to erase the P-Flash and D-Flash memory
5. After the CCIF flag sets to indicate that the Erase All Blocks operation has completed, reset the MCU into special single chip mode
6. Delay while the BDM executes the Erase Verify All Blocks command write sequence to verify that the P-Flash and D-Flash memory are erased

If the P-Flash and D-Flash memory are verified as erased, the MCU will be unsecured. All BDM commands will now be enabled and the Flash security byte may be programmed to the unsecure state by continuing with the following steps:
7. Send BDM commands to execute the Program P-Flash command write sequence to program the Flash security byte to the unsecured state
8. Reset the MCU

13.5.3 Mode and Security Effects on Flash Command Availability

The availability of Flash module commands depends on the MCU operating mode and security state as shown in Table 13-27.

13.6 Initialization

On each system reset the Flash module executes a reset sequence which establishes initial values for the Flash Block Configuration Parameters, the FPROT and DFPROT protection registers, and the FOPT and FSEC registers. The Flash module reverts to using built-in default values that leave the module in a fully protected and secured state if errors are encountered during execution of the reset sequence. If a double bit fault is detected during the reset sequence, both MGSTAT bits in the FSTAT register will be set.

CCIF remains clear throughout the reset sequence. The Flash module holds off all CPU access for the initial portion of the reset sequence. While Flash memory reads and access to most Flash registers are possible when the hold is removed, writes to the FCCOBIX, FCCOBHI, and FCCOBOO registers are ignored. Completion of the reset sequence is marked by setting CCIF high which enables writes to the FCCOBIX, FCCOBHI, and FCCOBOO registers to launch any available Flash command.

If a reset occurs while any Flash command is in progress, that command will be immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed.
Chapter 14
Timer Module (TIM16B8CV2) Block Description

14.1 Introduction

The basic timer consists of a 16-bit, software-programmable counter driven by a enhanced programmable prescaler.

This timer can be used for many purposes, including input waveform measurements while simultaneously generating an output waveform. Pulse widths can vary from microseconds to many seconds.

This timer contains 8 complete input capture/output compare channels and one pulse accumulator. The input capture function is used to detect a selected transition edge and record the time. The output compare function is used for generating output signals or for timer software delays. The 16-bit pulse accumulator

- Correct reference: Figure 1-25 -> Figure 1-31
- Add description, “a counter overflow when TTOV[7] is set”, to be the condition of channel 7 override event.
- Phrase the description of OC7M to make it more explicit |
is used to operate as a simple event counter or a gated time accumulator. The pulse accumulator shares timer channel 7 when in event mode.

A full access for the counter registers or the input capture/output compare registers should take place in one clock cycle. Accessing high byte and low byte separately for all of these registers may not yield the same result as accessing them in one word.

### 14.1.1 Features

The TIM16B8CV2 includes these distinctive features:

- Eight input capture/output compare channels.
- Clock prescaling.
- 16-bit counter.
- 16-bit pulse accumulator.

### 14.1.2 Modes of Operation

- **Stop:** Timer is off because clocks are stopped.
- **Freeze:** Timer counter keep on running, unless TSFRZ in TSCR1 (0x0006) is set to 1.
- **Wait:** Counters keep on running, unless TSWAI in TSCR1 (0x0006) is set to 1.
- **Normal:** Timer counter keep on running, unless TEN in TSCR1 (0x0006) is cleared to 0.
14.1.3 Block Diagrams

Figure 14-1. TIM16B8CV2 Block Diagram
Figure 14-2. 16-Bit Pulse Accumulator Block Diagram

Figure 14-3. Interrupt Flag Setting
14.2 External Signal Description

The TIM16B8CV2 module has a total of eight external pins.

14.2.1 IOC7 — Input Capture and Output Compare Channel 7 Pin

This pin serves as input capture or output compare for channel 7. This can also be configured as pulse accumulator input.

14.2.2 IOC6 — Input Capture and Output Compare Channel 6 Pin

This pin serves as input capture or output compare for channel 6.

14.2.3 IOC5 — Input Capture and Output Compare Channel 5 Pin

This pin serves as input capture or output compare for channel 5.

14.2.4 IOC4 — Input Capture and Output Compare Channel 4 Pin

This pin serves as input capture or output compare for channel 4.

14.2.5 IOC3 — Input Capture and Output Compare Channel 3 Pin

This pin serves as input capture or output compare for channel 3.

14.2.6 IOC2 — Input Capture and Output Compare Channel 2 Pin

This pin serves as input capture or output compare for channel 2.
14.2.7 IOC1 — Input Capture and Output Compare Channel 1 Pin
This pin serves as input capture or output compare for channel 1.

14.2.8 IOC0 — Input Capture and Output Compare Channel 0 Pin
This pin serves as input capture or output compare for channel 0.

NOTE
For the description of interrupts see Section 14.6, “Interrupts”.

14.3 Memory Map and Register Definition
This section provides a detailed description of all memory and registers.

14.3.1 Module Memory Map
The memory map for the TIM16B8CV2 module is given below in Figure 14-5. The address listed for each register is the address offset. The total address for each register is the sum of the base address for the TIM16B8CV2 module and the address offset for each register.

14.3.2 Register Descriptions
This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

<td>Output Compare 7 Data — A channel 7 event, which can be a counter overflow when TTOV[7] is set or a successful output compare on channel 7, can cause bits in the output compare 7 data register to transfer to the timer port data register depending on the output compare 7 mask register.</td>
</tr>
</tbody>
</table>

#### 14.3.2.5 Timer Count Register (TCNT)

The 16-bit main timer is an up counter.

A full access for the counter register should take place in one clock cycle. A separate read/write for high byte and low byte will give a different result than accessing them as a word.

Read: Anytime
Write: Has no meaning or effect in the normal mode; only writable in special modes \(\text{test}_\text{mode} = 1\).

The period of the first count after a write to the TCNT registers may be a different size because the write is not synchronized with the prescaler clock.

</table>
| 7:0 OMx | Output Mode — These eight pairs of control bits are encoded to specify the output action to be taken as a result of a successful OCx compare. When either OMx or OLx is 1, the pin associated with OCx becomes an output tied to OCx.  
Note: To enable output action by OMx bits on timer port, the corresponding bit in OC7M should be cleared. For an output line to be driven by an OCx the OCPDx must be cleared. |
| 7:0 OLx | Output Level — These eight pairs of control bits are encoded to specify the output action to be taken as a result of a successful OCx compare. When either OMx or OLx is 1, the pin associated with OCx becomes an output tied to OCx.  
Note: To enable output action by OLx bits on timer port, the corresponding bit in OC7M should be cleared. For an output line to be driven by an OCx the OCPDx must be cleared. |

</thead>
<tbody>
<tr>
<td>1 PAOVF</td>
<td><strong>Pulse Accumulator Overflow Flag</strong> — Set when the 16-bit pulse accumulator overflows from 0xFFFF to 0x0000. Clearing this bit requires writing a one to this bit in the PAFLG register while TEN bit of TSCR1 or PAEN bit of PACTL register is set to one.</td>
</tr>
<tr>
<td>0 PAIF</td>
<td><strong>Pulse Accumulator Input edge Flag</strong> — Set when the selected edge is detected at the IOC7 input pin. In event mode the event edge triggers PAIF and in gated time accumulation mode the trailing edge of the gate signal at the IOC7 input pin triggers PAIF. Clearing this bit requires writing a one to this bit in the PAFLG register while TEN bit of TSCR1 or PAEN bit of PACTL register is set to one. Any access to the PACNT register will clear all the flags in this register when TFFCA bit in register TSCR(0x0006) is set.</td>
</tr>
</tbody>
</table>

Read: Anytime  
Write: Anytime

These registers contain the number of active input edges on its input pin since the last reset.

When PACNT overflows from 0xFFFF to 0x0000, the Interrupt flag PAOVF in PAFLG (0x0021) is set. Full count register access should take place in one clock cycle. A separate read/write for high byte and low byte will give a different result than accessing them as a word.

**NOTE**  
Reading the pulse accumulator counter registers immediately after an active edge on the pulse accumulator input pin may miss the last count because the input has to be synchronized with the bus clock first.
14.3.2.18 Output Compare Pin Disconnect Register (OCPD)

Module Base + 0x002C

14.4 Functional Description

This section provides a complete functional description of the timer TIM16B8CV2 block. Please refer to the detailed timer block diagram in Figure 14-30 as necessary.
14.4.1 Prescaler

The prescaler divides the bus clock by 1, 2, 4, 8, 16, 32, 64 or 128. The prescaler select bits, PR[2:0], select the prescaler divisor. PR[2:0] are in timer system control register 2 (TSCR2).
The prescaler divides the bus clock by a prescalar value. Prescaler select bits PR[2:0] of in timer system control register 2 (TSCR2) are set to define a prescalar value that generates a divide by 1, 2, 4, 8, 16, 32, 64 and 128 when the PRNT bit in TSCR1 is disabled.

By enabling the PRNT bit of the TSCR1 register, the performance of the timer can be enhanced. In this case, it is possible to set additional prescaler settings for the main timer counter in the present timer by using PTPSR[7:0] bits of PTPSR register.

### 14.4.2 Input Capture

Clearing the I/O (input/output) select bit, IOSx, configures channel x as an input capture channel. The input capture function captures the time at which an external event occurs. When an active edge occurs on the pin of an input capture channel, the timer transfers the value in the timer counter into the timer channel registers, TCx.

The minimum pulse width for the input capture input is greater than two bus clocks.

An input capture on channel x sets the CxF flag. The CxI bit enables the CxF flag to generate interrupt requests. Timer module or Pulse Accumulator must stay enabled (TEN bit of TSCR1 or PAEN bit of PACTL register must be set to one) while clearing CxF (writing one to CxF).

### 14.4.3 Output Compare

Setting the I/O select bit, IOSx, configures channel x as an output compare channel. The output compare function can generate a periodic pulse with a programmable polarity, duration, and frequency. When the timer counter reaches the value in the channel registers of an output compare channel, the timer can set, clear, or toggle the channel pin if the corresponding OCPDx bit is set to zero. An output compare on channel x sets the CxF flag. The CxI bit enables the CxF flag to generate interrupt requests. Timer module or Pulse Accumulator must stay enabled (TEN bit of TSCR1 or PAEN bit of PACTL register must be set to one) while clearing CxF (writing one to CxF).

The output mode and level bits, OMx and OLx, select set, clear, toggle on output compare. Clearing both OMx and OLx results in no output compare action on the output compare channel pin.

Setting a force output compare bit, FOCx, causes an output compare on channel x. A forced output compare does not set the channel flag.

A channel 7 event, which can be a counter overflow when TTOV[7] is set or a successful output compare on channel 7, overrides output compares on all other output compare channels. The output compare 7 mask register masks the bits in the output compare 7 data register. The timer counter reset enable bit, TCRE, enables channel 7 output compares to reset the timer counter. A channel 7 output compare can reset the timer counter even if the IOC7 pin is being used as the pulse accumulator input.

Writing to the timer port bit of an output compare pin does not affect the pin state. The value written is stored in an internal latch. When the pin becomes available for general-purpose output, the last value written to the bit appears at the pin.
14.4.3.1 OC Channel Initialization

Internal register whose output drives OCx can be programmed before timer drives OCx. The desired state can be programmed to this Internal register by writing a one to CFORCx bit with TIOSx, OCPDx and TEN bits set to one. Setting OCPDx to zero allows Internal register to drive the programmed state to OCx. This allows a glitch free switch over of port from general purpose I/O to timer output once the OCPDx bit is set to zero.

14.4.4 Pulse Accumulator

The pulse accumulator (PACNT) is a 16-bit counter that can operate in two modes:

Event counter mode — Counting edges of selected polarity on the pulse accumulator input pin, PAI.

Gated time accumulation mode — Counting pulses from a divide-by-64 clock. The PAMOD bit selects the mode of operation.

The minimum pulse width for the PAI input is greater than two bus clocks.

14.4.5 Event Counter Mode

Clearing the PAMOD bit configures the PACNT for event counter operation. An active edge on the IOC7 pin increments the pulse accumulator counter. The PEDGE bit selects falling edges or rising edges to increment the count.

**NOTE**

The PACNT input and timer channel 7 use the same pin IOC7. To use the IOC7, disconnect it from the output logic by clearing the channel 7 output mode and output level bits, OM7 and OL7. Also clear the channel 7 output compare 7 mask bit, OC7M7.

The Pulse Accumulator counter register reflect the number of active input edges on the PACNT input pin since the last reset.

The PAOVF bit is set when the accumulator rolls over from 0xFFFF to 0x0000. The pulse accumulator overflow interrupt enable bit, PAOVI, enables the PAOVF flag to generate interrupt requests.

**NOTE**

The pulse accumulator counter can operate in event counter mode even when the timer enable bit, TEN, is clear.

14.4.6 Gated Time Accumulation Mode

Setting the PAMOD bit configures the pulse accumulator for gated time accumulation operation. An active level on the PACNT input pin enables a divided-by-64 clock to drive the pulse accumulator. The PEDGE bit selects low levels or high levels to enable the divided-by-64 clock.

The trailing edge of the active level at the IOC7 pin sets the PAIF. The PAI bit enables the PAIF flag to generate interrupt requests.
The pulse accumulator counter register reflect the number of pulses from the divided-by-64 clock since the last reset.

**NOTE**

The timer prescaler generates the divided-by-64 clock. If the timer is not active, there is no divided-by-64 clock.

### 14.5 Resets

The reset state of each individual bit is listed within Section 14.3, “Memory Map and Register Definition” which details the registers and their bit fields.

### 14.6 Interrupts

This section describes interrupts originated by the TIM16B8CV2 block. Table 14-24 lists the interrupts generated by the TIM16B8CV2 to communicate with the MCU.

<table>

1. Chip Dependent.

The TIM16B8CV2 uses a total of 11 interrupt vectors. The interrupt vector offsets and interrupt numbers are chip dependent.

#### 14.6.1 Channel [7:0] Interrupt (C[7:0]F)

This active high outputs will be asserted by the module to request a timer channel 7 – 0 interrupt to be serviced by the system controller.

#### 14.6.2 Pulse Accumulator Input Interrupt (PAOVI)

This active high output will be asserted by the module to request a timer pulse accumulator input interrupt to be serviced by the system controller.

#### 14.6.3 Pulse Accumulator Overflow Interrupt (PAOVF)

This active high output will be asserted by the module to request a timer pulse accumulator overflow interrupt to be serviced by the system controller.
14.6.4 Timer Overflow Interrupt (TOF)

This active high output will be asserted by the module to request a timer overflow interrupt to be serviced by the system controller.
Appendix A
Electrical Characteristics

A.1 General

This supplement contains the most accurate electrical information for the MC9S12P-Family microcontroller available at the time of publication.

This introduction is intended to give an overview on several common topics like power supply, current injection etc.

A.1.1 Parameter Classification

The electrical parameters shown in this supplement are guaranteed by various methods. To give the customer a better understanding the following classification is used and the parameters are tagged accordingly in the tables where appropriate.

NOTE

This classification is shown in the column labeled “C” in the parameter tables where appropriate.

P: Those parameters are guaranteed during production testing on each individual device.

C: Those parameters are achieved by the design characterization by measuring a statistically relevant sample size across process variations.

T: Those parameters are achieved by design characterization on a small sample size from typical devices under typical conditions unless otherwise noted. All values shown in the typical column are within this category.

D: Those parameters are derived mainly from simulations.

A.1.2 Power Supply

The VDDA, VSSA pin pairs supply the A/D converter and parts of the internal voltage regulator.

VDDR supplies the internal voltage regulator.

All VDDX pins are internally connected by metal.

All VSSX pins are internally connected by metal.

VDDA, VDDX and VSSA, VSSX are connected by diodes for ESD protection.
NOTE
In the following context \( V_{DD35} \) is used for either VDDA, VDDR, and VDDX; \( V_{SS35} \) is used for either VSSA and VSSX unless otherwise noted.

\( I_{DD35} \) denotes the sum of the currents flowing into the VDDA, VDDX and VDDR pins.

A.1.3 Pins

There are four groups of functional pins.

A.1.3.1 I/O Pins

The I/O pins have a level in the range of 3.15V to 5.5V. This class of pins is comprised of all port I/O pins, the analog inputs, BKGD and the \( \text{RESET} \) pins. Some functionality may be disabled.

A.1.3.2 Analog Reference

This group is made up by the VRH and VRL pins.

A.1.3.3 Oscillator

The pins EXTAL, XTAL dedicated to the oscillator have a nominal 1.8V level.

A.1.3.4 TEST

This pin is used for production testing only. The TEST pin must be tied to ground in all applications.

A.1.4 Current Injection

Power supply must maintain regulation within operating \( V_{DD35} \) or \( V_{DD} \) range during instantaneous and operating maximum current conditions. If positive injection current (\( V_{in} > V_{DD35} \)) is greater than \( I_{DD35} \), the injection current may flow out of \( V_{DD35} \) and could result in external power supply going out of regulation. Ensure external \( V_{DD35} \) load will shunt current greater than maximum injection current. This will be the greatest risk when the MCU is not consuming power; e.g., if no system clock is present, or if clock rate is very low which would reduce overall power consumption.

A.1.5 Absolute Maximum Ratings

Absolute maximum ratings are stress ratings only. A functional operation under or outside those maxima is not guaranteed. Stress beyond those limits may affect the reliability or cause permanent damage of the device.

This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (e.g., either \( V_{SS35} \) or \( V_{DD35} \)).
A.1.6  **ESD Protection and Latch-up Immunity**

All ESD testing is in conformity with CDF-AEC-Q100 stress test qualification for automotive grade integrated circuits. During the device qualification ESD stresses were performed for the Human Body Model (HBM) and the Charge Device Model.

A device will be defined as a failure if after exposure to ESD pulses the device no longer meets the device specification. Complete DC parametric and functional testing is performed per the applicable device specification at room temperature followed by hot temperature, unless specified otherwise in the device specification.

1. Beyond absolute maximum ratings device might be damaged.
2. All digital I/O pins are internally clamped to $V_{SSX}$ and $V_{DDX}$, or $V_{SSA}$ and $V_{DDA}$.
A.1.7 Operating Conditions

This section describes the operating conditions of the device. Unless otherwise noted those conditions apply to all the following data.

**NOTE**

Please refer to the temperature rating of the device (C, V, M) with regards to the ambient temperature $T_A$ and the junction temperature $T_J$. For power dissipation calculations refer to Section A.1.8, “Power Dissipation and Thermal Characteristics”.

</tbody>
</table>
NOTE

Operation is guaranteed when powering down until low voltage reset assertion.

**A.1.8 Power Dissipation and Thermal Characteristics**

Power dissipation and thermal characteristics are closely related. The user must assure that the maximum operating junction temperature is not exceeded. The average chip-junction temperature ($T_J$) in °C can be obtained from:

$$T_J = T_A + (P_D \cdot \Theta_{JA})$$

$T_J$ = Junction Temperature, [°C]  
$T_A$ = Ambient Temperature, [°C]  
$P_D$ = Total Chip Power Dissipation, [W]  
$\Theta_{JA}$ = Package Thermal Resistance, [°C/W]  

The total power dissipation can be calculated from:

$$P_D = P_{INT} + P_{IO}$$

$P_{INT}$ = Chip Internal Power Dissipation, [W]  

$$P_{IO} = \sum_{i} R_{DSON} \cdot I_{IO_i}^2$$
PIO is the sum of all output currents on I/O ports associated with VDDX, whereby

\[ R_{DSON} = \frac{V_{OL}}{I_{OL}} \text{; for outputs driven low} \]

\[ R_{DSON} = \frac{V_{DD35} - V_{OH}}{I_{OH}} \text{; for outputs driven high} \]

\[ P_{INT} = I_{DDR} \cdot V_{DDR} + I_{DDA} \cdot V_{DDA} \]

</table>

1. The values for thermal resistance are achieved by package simulations
2. Junction to ambient thermal resistance, θ_JA was simulated to be equivalent to the JEDEC specification JESD51-2 in a horizontal configuration in natural convection.
3. Junction to ambient thermal resistance, θ_JA was simulated to be equivalent to the JEDEC specification JESD51-7 in a horizontal configuration in natural convection.
4. Junction to case thermal resistance was simulated to be equivalent to the measured values using the cold plate technique with the cold plate temperature used as the “case” temperature. This basic cold plate measurement technique is described by MIL-STD 883D, Method 1012.1. This is the correct thermal metric to use to calculate thermal performance when the package is being used with a heat sink.

5. Thermal characterization parameter $\Psi_{JT}$ is the “resistance” from junction to reference point thermocouple on top center of the case as defined in JESD51-2. $\Psi_{JT}$ is a useful value to use to estimate junction temperature in a steady state customer environment.

6. Junction to case thermal resistance was simulated to be equivalent to the measured values using the cold plate technique with the cold plate temperature used as the “case” temperature. This basic cold plate measurement technique is described by MIL-STD 883D, Method 1012.1. This is the correct thermal metric to use to calculate thermal performance when the package is being used with a heat sink.

7. Thermal characterization parameter $\Psi_{JT}$ is the “resistance” from junction to reference point thermocouple on top center of the case as defined in JESD51-2. $\Psi_{JT}$ is a useful value to use to estimate junction temperature in a steady state customer environment.
A.1.9  I/O Characteristics

This section describes the characteristics of all I/O pins except EXTAL, XTAL, TEST and supply pins.

1. Maximum leakage current occurs at maximum operating temperature. Current decreases by approximately one-half for each 8°C to 12°C in the temperature range from 50°C to 125°C.
2. Refer to Section A.1.4, "Current Injection" for more details.
3. Parameter only applies in stop or pseudo stop mode.

A.1.10 Supply Currents

This section describes the current consumption characteristics of the device as well as the conditions for the measurements.

A.1.10.1 Measurement Conditions

Run current is measured on VDDR pin. It does not include the current to drive external loads. Unless otherwise noted the currents are measured in special single chip mode and the CPU code is executed from RAM. For Run and Wait current measurements PLL is on and the reference clock is the IRC1M trimmed to 1MHz. The bus frequency is 32MHz and the CPU frequency is 64MHz. Table A-8., Table A-9. and Table A-10. show the configuration of the CPMU module and the peripherals for Run, Wait and Stop current measurement.

### A.2 ATD Characteristics

This section describes the characteristics of the analog-to-digital converter.

#### A.2.1 ATD Operating Characteristics

The Table A-14 and Table A-15 show conditions under which the ATD operates.

The following constraints exist to obtain full-scale, full range results:

\[
V_{\text{SSA}} \leq V_{\text{RL}} \leq V_{\text{IN}} \leq V_{\text{RH}} \leq V_{\text{DDA}}.
\]

This constraint exists since the sample buffer amplifier can not drive beyond the power supply levels that it ties to. If the input level goes outside of this range it will effectively be clipped.

</tr>
</tbody>
</table>

1. Full accuracy is not guaranteed when differential voltage is less than 4.50 V
2. When converting in Stop Mode (IQLKSTP=1) an ATD Stop Recovery time $t_{\text{ATDSTPRC}}$ is required to switch back to bus clock based ATDCLK when leaving Stop Mode. Do not access ATD registers during this time.
3. The minimum time assumes a sample time of 4 ATD clock cycles. The maximum time assumes a sample time of 24 ATD clock cycles and the discharge feature (SMP_DIS) enabled, which adds 2 ATD clock cycles.
A.2.2 Factors Influencing Accuracy

Source resistance, source capacitance and current injection have an influence on the accuracy of the ATD. A further factor is that PortAD pins that are configured as output drivers switching.

A.2.2.1 Port AD Output Drivers Switching

PortAD output drivers switching can adversely affect the ATD accuracy whilst converting the analog voltage on other PortAD pins because the output drivers are supplied from the VDDA/VSSA ATD supply pins. Although internal design measures are implemented to minimize the effect of output driver noise, it is recommended to configure PortAD pins as outputs only for low frequency, low load outputs. The impact on ATD accuracy is load dependent and not specified. The values specified are valid under condition that no PortAD output drivers switch during conversion.

A.2.2.2 Source Resistance

Due to the input pin leakage current as specified in Table A-6 and Table A-7 in conjunction with the source resistance there will be a voltage drop from the signal source to the ATD input. The maximum source resistance $R_S$ specifies results in an error (10-bit resolution) of less than 1/2 LSB (2.5 mV) at the maximum leakage current. If device or operating conditions are less than worst case or leakage-induced error is acceptable, larger values of source resistance of up to 10Kohm are allowed.

A.2.2.3 Source Capacitance

When sampling an additional internal capacitor is switched to the input. This can cause a voltage drop due to charge sharing with the external and the pin capacitance. For a maximum sampling error of the input voltage $\leq 1$LSB (10-bit resolution), then the external filter capacitor, $C_f \geq 1024 \times (C_{INS}–C_{INN})$.

A.2.2.4 Current Injection

There are two cases to consider.

1. A current is injected into the channel being converted. The channel being stressed has conversion values of $3FF$ (in 10-bit mode) for analog inputs greater than $V_{RH}$ and $000$ for values less than $V_{RL}$ unless the current is higher than specified as disruptive condition.

2. Current is injected into pins in the neighborhood of the channel being converted. A portion of this current is picked up by the channel (coupling ratio $K$). This additional current impacts the accuracy of the conversion depending on the source resistance.

The additional input voltage error on the converted channel can be calculated as:

$$V_{ERR} = K \times R_S \times I_{INJ}$$

with $I_{INJ}$ being the sum of the currents injected into the two pins adjacent to the converted channel.
A.2.3 ATD Accuracy

Table A-16 and Table A-17 specifies the ATD conversion performance excluding any errors due to current injection, input capacitance and source resistance.
A.2.3.1 ATD Accuracy Definitions

For the following definitions see also Figure A-1.
Differential non-linearity (DNL) is defined as the difference between two adjacent switching steps.

\[
DNL(i) = \frac{V_i - V_{i-1}}{1\text{LSB}} - 1
\]

The integral non-linearity (INL) is defined as the sum of all DNLs:

\[
INL(n) = \sum_{i=1}^{n} DNL(i) = \frac{V_n - V_0}{1\text{LSB}} - n
\]
Figure A-1. ATD Accuracy Definitions

NOTE
Figure A-1 shows only definitions, for specification values refer to Table A-16 and Table A-17.
### Table A-16. ATD Conversion Performance 5V range

Conditions are shown in Table A-4, unless otherwise noted. \( V_{\text{REF}} = V_{\text{RH}} - V_{\text{RL}} = 5.12 \)V. \( f_{\text{ATDCLK}} = 8.0\)MHz. The values are tested to be valid with no PortAD output drivers switching simultaneous with conversions.

2. These values include the quantization error which is inherently 1/2 count for any A/D converter.
A.3 NVM

A.3.1 Timing Parameters

The time base for all NVM program or erase operations is derived from the bus clock using the FCLKDIV register. The frequency of this derived clock must be set within the limits specified as $f_{NVMOP}$. The NVM module does not have any means to monitor the frequency and will not prevent program or erase operation at frequencies above or below the specified minimum. When attempting to program or erase the NVM module at a lower frequency, a full program or erase transition is not assured.

The following sections provide equations which can be used to determine the time required to execute specific flash commands. All timing parameters are a function of the bus clock frequency, $f_{NVMBUS}$. All program and erase times are also a function of the NVM operating frequency, $f_{NVMOP}$. A summary of key timing parameters can be found in Table A-18.

A.3.1.1 Erase Verify All Blocks (Blank Check) (FCMD=0x01)

The time required to perform a blank check on all blocks is dependent on the location of the first non-blank word starting at relative address zero. It takes one bus cycle per phrase to verify plus a setup of the command. Assuming that no non-blank location is found, then the time to erase verify all blocks is given by:

$$t_{check} = 35500 \cdot \frac{1}{f_{NVMBUS}}$$

A.3.1.2 Erase Verify Block (Blank Check) (FCMD=0x02)

The time required to perform a blank check is dependent on the location of the first non-blank word starting at relative address zero. It takes one bus cycle per phrase to verify plus a setup of the command. Assuming that no non-blank location is found, then the time to erase verify a P-Flash block is given by:

$$t_{pcheck} = 33500 \cdot \frac{1}{f_{NVMBUS}}$$

Assuming that no non-blank location is found, then the time to erase verify a D-Flash block is given by:

$$t_{dcheck} = 2800 \cdot \frac{1}{f_{NVMBUS}}$$
A.3.1.3  Erase Verify P-Flash Section (FCMD=0x03)

The maximum time to erase verify a section of P-Flash depends on the number of phrases being verified ($N_{VP}$) and is given by:

$$t \approx (450 + N_{VP}) \cdot \frac{1}{f_{NVMBUS}}$$

A.3.1.4  Read Once (FCMD=0x04)

The maximum read once time is given by:

$$t = 400 \cdot \frac{1}{f_{NVMBUS}}$$

A.3.1.5  Program P-Flash (FCMD=0x06)

The programming time for a single phrase of four P-Flash words and the two seven-bit ECC fields is dependent on the bus frequency, $f_{NVMBUS}$, as well as on the NVM operating frequency, $f_{NVMOP}$.

The typical phrase programming time is given by:

$$t_{PPGM} = 164 \cdot \frac{1}{f_{NVMOP}} + 2000 \cdot \frac{1}{f_{NVMBUS}}$$

The maximum phrase programming time is given by:

$$t_{PPGM} = 164 \cdot \frac{1}{f_{NVMOP}} + 2500 \cdot \frac{1}{f_{NVMBUS}}$$

A.3.1.6  Program Once (FCMD=0x07)

The maximum time required to program a P-Flash Program Once field is given by:

$$t = 164 \cdot \frac{1}{f_{NVMOP}} + 2150 \cdot \frac{1}{f_{NVMBUS}}$$

A.3.1.7  Erase All Blocks (FCMD=0x08)

The time required to erase all blocks is given by:

$$t_{mass} = 100100 \cdot \frac{1}{f_{NVMOP}} + 70000 \cdot \frac{1}{f_{NVMBUS}}$$
A.3.1.8  Erase P-Flash Block (FCMD=0x09)

The time required to erase the P-Flash block is given by:

\[ t_{pmass} = 100100 \cdot \frac{1}{f_{NVMOP}} + 67000 \cdot \frac{1}{f_{NVMBUS}} \]

A.3.1.9  Erase P-Flash Sector (FCMD=0x0A)

The typical time to erase a 512-byte P-Flash sector is given by:

\[ t_{pera} = 20020 \cdot \frac{1}{f_{NVMOP}} + 700 \cdot \frac{1}{f_{NVMBUS}} \]

The maximum time to erase a 512-byte P-Flash sector is given by:

\[ t_{pera} = 20020 \cdot \frac{1}{f_{NVMOP}} + 1400 \cdot \frac{1}{f_{NVMBUS}} \]

A.3.1.10  Unsecure Flash (FCMD=0x0B)

The maximum time required to erase and unsecure the Flash is given by:

for 128 Kbyte P-Flash and 4 Kbyte D-Flash

\[ t_{uns} = 100100 \cdot \frac{1}{f_{NVMOP}} + 70000 \cdot \frac{1}{f_{NVMBUS}} \]

A.3.1.11  Verify Backdoor Access Key (FCMD=0x0C)

The maximum verify backdoor access key time is given by:

\[ t = 400 \cdot \frac{1}{f_{NVMBUS}} \]

A.3.1.12  Set User Margin Level (FCMD=0x0D)

The maximum set user margin level time is given by:

\[ t = 350 \cdot \frac{1}{f_{NVMBUS}} \]
A.3.1.13  Set Field Margin Level (FCMD=0x0E)

The maximum set field margin level time is given by:

\[ t = 350 \cdot \frac{1}{f_{\text{NVMBUS}}} \]

A.3.1.14  Erase Verify D-Flash Section (FCMD=0x10)

The time required to Erase Verify D-Flash for a given number of words \( N_W \) is given by:

\[ t_{\text{dcheck}} = (450 + N_W) \cdot \frac{1}{f_{\text{NVMBUS}}} \]

A.3.1.15  Program D-Flash (FCMD=0x11)

D-Flash programming time is dependent on the number of words being programmed and their location with respect to a row boundary since programming across a row boundary requires extra steps. The D-Flash programming time is specified for different cases: 1,2,3,4 words and 4 words across a row boundary.

The typical D-Flash programming time is given by the following equation, where \( N_W \) denotes the number of words; \( BC=0 \) if no row boundary is crossed and \( BC=1 \) if a row boundary is crossed:

\[ t_{\text{dpgm}} = \left( 14 + (54 \cdot N_W) + (14 \cdot BC) \right) \cdot \frac{1}{f_{\text{NVMOP}}} + \left( 500 + (525 \cdot N_W) + (100 \cdot BC) \right) \cdot \frac{1}{f_{\text{NVMBUS}}} \]

The maximum D-Flash programming time is given by:

\[ t_{\text{dpgm}} = \left( 14 + (54 \cdot N_W) + (14 \cdot BC) \right) \cdot \frac{1}{f_{\text{NVMOP}}} + \left( 500 + (750 \cdot N_W) + (100 \cdot BC) \right) \cdot \frac{1}{f_{\text{NVMBUS}}} \]

A.3.1.16  Erase D-Flash Sector (FCMD=0x12)

Typical D-Flash sector erase times, expected on a new device where no margin verify fails occur, is given by:

\[ t_{\text{dera}} = 5025 \cdot \frac{1}{f_{\text{NVMOP}}} + 700 \cdot \frac{1}{f_{\text{NVMBUS}}} \]

Maximum D-Flash sector erase times is given by:

\[ t_{\text{dera}} = 20100 \cdot \frac{1}{f_{\text{NVMOP}}} + 3400 \cdot \frac{1}{f_{\text{NVMBUS}}} \]
The D-Flash sector erase time is ~5ms on a new device and can extend to ~20ms as the flash is cycled.

2. Maximum program and erase times are based on minimum f_{NVMOP} and maximum f_{NVMBUS}
3. t_{cyc} = 1 / f_{NVMBUS}
4. Typical value for a new device

### A.3.2 NVM Reliability Parameters

The reliability of the NVM blocks is guaranteed by stress test during qualification, constant process monitors and burn-in to screen early life failures.

The data retention and program/erase cycling failure rates are specified at the operating conditions noted. The program/erase cycle count on the sector is incremented every time a sector or mass erase event is executed.
NOTE

All values shown in Table A-19 are preliminary and subject to further characterization.

Table A-19. NVM Reliability Characteristics

<td>500K$^3$</td>
<td>—</td>
<td>Cycles</td>
</tr>
</tbody>
</table>

1. $T_{\text{avg}}$ does not exceed 85°C in a typical temperature profile over the lifetime of a consumer, industrial or automotive application.

2. Typical data retention values are based on intrinsic capability of the technology measured at high temperature and de-rated to 25°C using the Arrhenius equation. For additional information on how Freescale defines Typical Data Retention, please refer to Engineering Bulletin EB618.

3. Spec table quotes typical endurance evaluated at 25°C for this product family. For additional information on how Freescale defines Typical Endurance, please refer to Engineering Bulletin EB619.

A.4 Phase Locked Loop

A.4.1 Jitter Definitions

With each transition of the feedback clock, the deviation from the reference clock is measured and input voltage to the VCO is adjusted accordingly. The adjustment is done continuously with no abrupt changes in the VCOCLK frequency. Noise, voltage, temperature and other factors cause slight variations in the control loop resulting in a clock jitter. This jitter affects the real minimum and maximum clock periods as illustrated in Figure A-2.
The relative deviation of $t_{\text{nom}}$ is at its maximum for one clock period, and decreases towards zero for larger number of clock periods (N).

Defining the jitter as:

$$J(N) = \max \left( 1 - \frac{t_{\text{max}}(N)}{N \cdot t_{\text{nom}}} , 1 - \frac{t_{\text{min}}(N)}{N \cdot t_{\text{nom}}} \right)$$

For $N < 100$, the following equation is a good fit for the maximum jitter:

$$J(N) = \frac{j_1}{\sqrt{N}}$$

NOTE

On timers and serial modules a prescaler will eliminate the effect of the jitter to a large extent.

</tbody>
</table>

1. Monitors VDDA, active only in Full Performance Mode. Indicates I/O & ADC performance degradation due to low supply voltage.
2. Device functionality is guaranteed on power down to the LVR assert level
3. Monitors VDDX, active only in Full Performance Mode. MCU is monitored by the POR in RPM (see Figure A-4)
4. The API Trimming APITR[5:0] bits must be set so that $f_{ACLK}$=10KHz.
5. A hysteresis is guaranteed by design

NOTE

The LVR monitors the voltages $V_{DD}$, $V_{DDF}$ and $V_{DDX}$. As soon as voltage drops on these supplies which would prohibit the correct function of the microcontroller, the LVR is triggering a reset.

A.9 Chip Power-up and Voltage Drops

LVI (low voltage interrupt), POR (power-on reset) and LVRs (low voltage reset) handle chip power-up or drops of the supply voltage.

Appendix B
Ordering Information

The following figure provides an ordering partnumber example for the devices covered by this data book. There are two options when ordering a device. Customers must choose between ordering either the mask-specific partnumber or the generic / mask-independent partnumber. Ordering the mask-specific partnumber enables the customer to specify which particular maskset they will receive whereas ordering the generic maskset means that FSL will ship the currently preferred maskset (which may change over time).

In either case, the marking on the device will always show the generic / mask-independent partnumber and the mask set number.

NOTE
The mask identifier suffix and the Tape & Reel suffix are always both omitted from the partnumber which is actually marked on the device.

For specific partnumbers to order, please contact your local sales office. The below figure illustrates the structure of a typical mask-specific ordering number for the MC9S12P-Family devices.

---

**Tape & Reel:**
- R = Tape & Reel
- No R = No Tape & Reel

**Package Option:**
- FT = 48 QFN
- LH = 64 LQFP
- QK = 80 QFP

**Temperature Option:**
- C = -40°C to 85°C
- V = -40°C to 105°C
- M = -40°C to 125°C

**Maskset identifier Suffix:**
- First digit usually references wafer fab
- Second digit usually differentiates mask rev
  (This suffix is omitted in generic partnumbers)

**Device Title**

**Controller Family**

**Main Memory Type:**
- 9 = Flash
- 3 = ROM (if available)

**Status / Partnumber type:**
- S or SC = Maskset specific partnumber
- MC = Generic / mask-independent partnumber
- P or PC = prototype status (pre qualification)
Appendix C
Package Information

This section provides the physical dimensions of the MC9S12P-Family packages.

NOTE
The exposed pad of the 48 QFN package should be attached to Vss ground plane.

NOTES:

2. CONTROLLING DIMENSION: MILLIMETER.

3. DATUM PLANE "H" IS LOCATED AT BOTTOM OF LEAD AND IS COINCIDENT WITH THE LEAD WHERE THE LEAD EXITS THE PLASTIC BODY AT THE BOTTOM OF THE PARTING LINE.

4. DATUMS A-B AND "D" TO BE DETERMINED AT DATUM PLANE "H".

\[ \text{DIMENSIONS TO BE DETERMINED AT SEATING PLANE "C".} \]

\[ \text{DIMENSIONS DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.25 PER SIDE. DIMENSIONS DO INCLUDE MOLD MISMATCH AND ARE DETERMINED AT DATUM PLANE "H".} \]

\[ \text{DIMENSION DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL BE 0.08 TOTAL IN EXCESS OF THE DIMENSION AT MAXIMUM MATERIAL CONDITION. DAMBAR CANNOT BE LOCATED ON THE LOWER RADIUS OR THE FOOT.} \]

**PACKAGE INFORMATION**

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor 539
NOTES:

1. ALL DIMENSIONS ARE IN MILLIMETERS.
3. THE COMPLETE JEDEC DESIGNATOR FOR THIS PACKAGE IS: HF—PQFN.
4. MOLD SURFACE ROUGHNESS IS 0.8~1.0m(Ra).
5. COPLANARITY APPLIES TO LEADS AND DIE ATTACH PAD.
6. FOR ANVIL SINGULATED QFN PACKAGES, MAXIMUM DRAFT ANGLE IS 12°.
7. MIN METAL GAP SHOULD BE 0.25MM.

TITLE: THERMALLY ENHANCED QUAD FLAT NON—LEADED PACKAGE (QFN), 48 TERMINAL, 0.5 PITCH (7 X 7 X 1), PUNCH SINGULATION
CASE NUMBER: 1958—01
STANDARD: JEDEC MO—220 VKKD—2
PACKAGE CODE: 6232 SHEET: 3 OF 4
C.3 64 LQFP Package Mechanical Outline

MECHANICAL OUTLINE

TITLE: 64LD LQFP, 10 X 10 X 1.4 PKG, 0.5 PITCH, CASE OUTLINE

DOCUMENT NO: 9BASS23234W  REV: E
CASE NUMBER: 840F-02        11 AUG 2006
STANDARD: JEDEC MS-026 BCD

S12P-Family Reference Manual, Rev. 1.13

Freescale Semiconductor
NOTES:
1. DIMENSIONS ARE IN MILLIMETERS.
3. DATUMS A, B AND D TO BE DETERMINED AT DATUM PLANE H.
4. DIMENSIONS TO BE DETERMINED AT SEATING PLANE C.
5. THIS DIMENSION DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL NOT CAUSE THE LEAD WIDTH TO EXCEED THE UPPER LIMIT BY MORE THAN 0.08 mm AT MAXIMUM MATERIAL CONDITION. DAMBAR CANNOT BE LOCATED ON THE LOWER RADIUS OR THE FOOT. MINIMUM SPACE BETWEEN PROTRUSION AND ADJACENT LEAD SHALL NOT BE LESS THAN 0.07 mm.
6. THIS DIMENSION DOES NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.25 mm PER SIDE. THIS DIMENSION IS MAXIMUM PLASTIC BODY SIZE DIMENSION INCLUDING MOLD MISMATCH.
7. EXACT SHAPE OF EACH CORNER IS OPTIONAL.
8. THESE DIMENSIONS APPLY TO THE FLAT SECTION OF THE LEAD BETWEEN 0.1 mm AND 0.25 mm FROM THE LEAD TIP.
